

LANDFIRE 2001 and 2008 Refresh

Geographic Area Report

Southeast

December 2011

Executive Summary

The LANDFIRE National Project (LF_1.0.0) was successfully completed in 2009. The goal of LANDFIRE National was to generate consistent 2001 vintage 30 meter spatial data sets for all 50 States for fire and other natural resource applications. This report highlights results from the continuation of LANDFIRE as a program to update the spatial data layers through 2008. The focus of this phase of the program was to improve the data products and account for vegetation change across the landscape caused by wildland fire, fuel and vegetation treatments, and management. In addition, changes caused by insects and disease, storms, invasive plants, and other natural or anthropogenic events were incorporated when data were available. This report describes the LANDFIRE 2001/2008 Refresh effort to update existing map layers to reflect more current conditions, focusing primarily on vegetation changes. The effort incorporated user feedback and new data, producing two comprehensive Refresh data product sets:

1. LANDFIRE 2001 Refresh (LF_1.0.5) enhanced LANDFIRE map layers by incorporating user feedback and additional data to provide a foundation to update data to 2008. It was also designed to provide users with a data set to help facilitate comparisons between 2001 and 2008 (i.e. Refresh LF_1.1.0) data sets.
2. LANDFIRE 2008 Refresh (LF_1.1.0) updated map layers to reflect vegetation changes and disturbances that occurred between 1999 and 2008.

In this report, we (1) address the background and provide details pertaining to why there are two Refresh data sets, (2) explain the requirements, planning, and procedures behind the completion and delivery of the updated products for each of the data product sets, (3) show and describe results, and (4) provide case studies illustrating the performance of LANDFIRE National, LANDFIRE 2001 Refresh and LANDFIRE 2008 Refresh (LF_1.1.0) data products on some example wildland fires.

1.0 Introduction

1.1 LANDFIRE Program

LANDFIRE (LF), also known as Landscape Fire and Resource Management Planning Tools, is a joint program between the wildland fire management programs of the United States Department of Agriculture (USDA) Forest Service (USFS) and the United States Department of the Interior (DOI), including the following bureaus: the U.S. Geological Survey (USGS), the Bureau of Indian Affairs (BIA), the Bureau of Land Management (BLM), the Fish and Wildlife Service (FWS), and the National Park Service (NPS). The Nature Conservancy (TNC) serves as a cooperating partner. LF applies consistent methodologies and processes to create comprehensive spatial data and models describing vegetation and wildland fire/fuel characteristics across the United States. Mapped data products are based on Landsat satellite imagery and an extensive database of field-reference data, including USFS Forest Inventory Analysis (FIA) data.

LF provides the first implementation of methodologies and processes to develop and combine intermediate scale (30 m) spatial vegetation and fire information consistently across the entire United States. Such a suite of integrated vegetation, fuel, and fire regime data sets has not previously been created by the public or private sectors. LF data products facilitate National and regional (large landscape level) fire planning activities and the reporting of wildland fire management activities. LF products provide managers with the data needed for collaborative, landscape-scale, cross-boundary, interagency planning and implementation. LF data support land management to 1) identify fuel where fire hazards and fire risks to local communities may be located, 2) identify vegetation and fuel conditions where rehabilitation may benefit fire-dependent landscapes, 3) prioritize resources for national budget formulation and allocation, and 4) enhance management knowledge of fire behavior to improve firefighting safety. Programs within the wildland fire community that use LF data include the National Cohesive Wildland Fire Management Strategy, the Wildland Fire Decision Support System, Fire Program Analysis, and the Hazardous Fuel Prioritization and Allocation System.

While LF has proven highly valuable for the wildland fire community, it also provides value for other land management disciplines. LF data products provide an informational foundation that supports many diverse applications, including land management planning, environmental analyses, biological evaluations, monitoring, and resource assessments. Moreover, LF data are being considered as a key information input to a range of Federal interagency carbon sequestration and climate research initiatives. LF products are used in the land and resource management domains for setting strategic direction, supporting resource and staffing determinations, designing conservation management activities, and assessing risks to the environment and communities.

1.2 LANDFIRE Versions

In an effort to address user feedback and leadership direction, the LF team started from the base collection of data products developed during the LF National Project (circa 2001) to provide an updated collection of LF products. As such, different versions of LF data products were developed, requiring the creation of a data versioning specification. The data versioning table, available on the LF website

Introduction

(http://www.landfire.gov/version_comparison.php), assists users in understanding the differences among the various versions of LF data available on the LF Data Distribution Site (DDS). When LF data products are updated in the future, most of the versions currently available will be removed from the DDS and archived. Previous versions will be made available upon request. At any given point in time, there will be at most three versions of the data products available from the DDS. These will remain available for download on the DDS until the next product update has been completed.

1.2.1 LANDFIRE National (LF 1.0.0) circa 2001

LF National (LF_1.0.0) constitutes the first complete LF mapping of all geospatial data products for the Nation. LF National was a five-year project that incorporated Landsat imagery from 1999 through 2003 (circa 2001) and delivered data on vegetation characteristics and condition, fire behavior and effects, fuel models, historical fire regimes, and fire regime conditions class for the United States in 2009. In this report, we refer to this data set simply as “LANDFIRE National” or “LF National.” The final deliverables for LF National included all of the layers required to run fire behavior models, such as the Fire Area Simulator (FARSITE; Finney, 2004). Methods used were consistent and repeatable across all ownerships nationwide. The consistent and comprehensive nature of LF National methods ensured that data were nationally relevant, while the 30-meter grid resolution assured that data had local application. A modified suite of the LF National data products was delivered for Alaska and Hawaii.

1.2.2 LANDFIRE 2001 (LF 1.0.5) and 2008 (LF 1.1.0) Refresh

The LF 2001/2008 Refresh represents the initial effort to enhance and update LF layers to maintain the currency of the data sets across all 50 States. These versions were produced in tandem, starting in fall 2009 with the LF 2001 Refresh (LF_1.0.5), and finishing in calendar year 2011 with the LF 2008 Refresh (LF_1.1.0). LF 2001/2008 enhancements and updates were developed to facilitate comparative analyses, evaluate trends, and potentially monitor changes over time. In this report, we use the following simplified terminology.

When the enhancement and update segments are referred to individually, we use:

- (enhancements) “LANDFIRE 2001” or “LF 2001” for LANDFIRE 2001 Refresh (LF_1.0.5)
- (updates) “LANDFIRE 2008” or “LF 2008” for LANDFIRE 2008 Refresh (LF_1.1.0)

When we refer to both of these segments together in a generic fashion, we use:

- “LANDFIRE 2001 and 2008” or “LANDFIRE 2001/2008”
- “LF 2001 and LF 2008” or “LF 2001/2008”

The LF 2001 version was implemented to enhance the LF National data set and provide a foundation upon which to build the updated geospatial data set.

The LF 2008 version was implemented to update the LF National data set to reflect changes from recent (1999-2008) natural disturbances (such as wildland fires) and management activities using Landsat imagery.

1.3 LANDFIRE 2001/2008

Introduction

The LF 2001 and LF 2008 components of the LF Program sustain and extend the investment value of the original LF National data products with enhancements and updates to the LF spatial data suite. LF 2001 addressed vegetation discrepancies and areas of concern detected after the initial mapping effort. Problems with LF National products identified by users included discrepancies in vegetated versus non-vegetated lands, vegetation/land use categories, vegetation structure, and water/riparian attribution. Enhancements to address these discrepancies were requested by stakeholders that use LF data. The map layers were enhanced in LF 2001 by leveraging additional data sources, such as Soil Survey Geographic (SSURGO) data.

LF 2008 focused on updates to the suite of LF data products to reflect 2008 conditions. This focus was on updating landscape-level vegetation changes, such as those resulting from wildland fire, fuel and vegetation / silvicultural treatments, mortality from insects and disease, storm damage, invasive plants, and other natural or anthropogenic events where relevant data were available that occurred in the years from 1999 - 2008. To create LF 2008 products, Landsat imagery was used to detect vegetation change and landscape disturbance. A collection of recent natural disturbance and land management activities was compiled and stored in a spatial database. These products were combined along with other data sets to update existing vegetation and fuel layers. These updated vegetation and fuels layers were then used to update other LF data products. LF 2008 did not use new imagery to remap the entire landscape only to identify vegetation change or disturbance. To update products, LF 2001/2008 leveraged information and comments received through various sources, such as the LF help desk (<http://www.landfire.gov/contactus.php>), after action reviews, fuel calibration workshops, and lessons learned examples. LF 2001/2008 products have been used as inputs to strategic wildland fire management decision support systems and are expected to improve the relevance and reliability of the outcomes generated by these systems.

Nine geographic areas (GeoAreas; Figure 1) were defined to include all of the original mapping zones used from the National Land Cover Database (NLCD; based loosely on Omernik, 1987) for use in the LF National effort. The application of mapping zones as a pre-classification stratification method has been used in many mapping approaches (Homer et al. 1997; Homer et al. 2004). Research has shown that carefully defined mapping zones maximize spectral differentiation, provide a means to facilitate partitioning the workload into logical units, simplify post-classification modeling and improve classification accuracy (Homer et al. 2004). The GeoAreas were not intended to represent standardized analysis units or reporting extents. The primary purpose of the GeoAreas and mapping zones was to define ecologically relevant divisions for data acquisition and production planning.

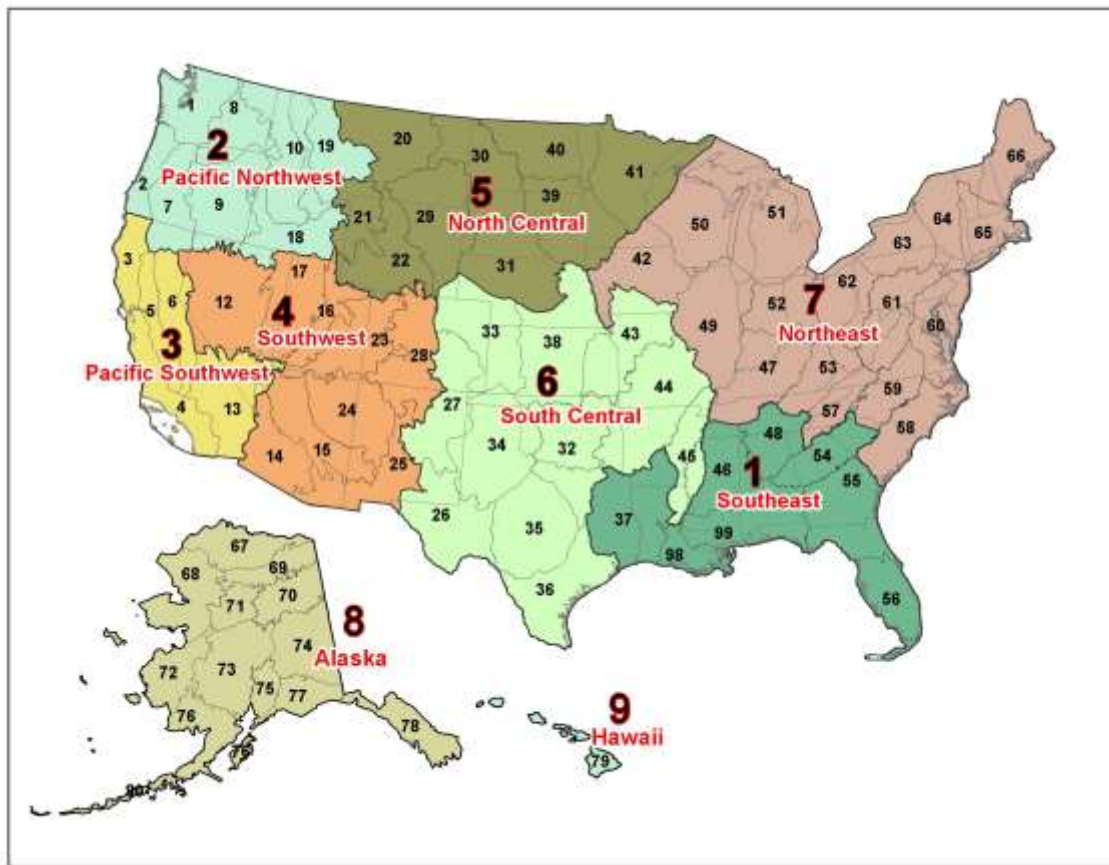

Figure 1 – Map of LF 2001/2008 GeoAreas according to the schedule. This image shows the nine GeoArea boundaries, which are composed of National Land Cover Database 2001 mapping zones (numbered units); state boundaries are included for reference. GeoArea numbers and corresponding colors relate to the schedule in Table 1 below.

1.4 LANDFIRE 2001/2008 Statement of Work and Work Breakdown Structure

LF 2001/2008 used conventional best practices in project and program management to address the organizational structure, scheduling, and implementation procedures. The effort was faced with uncertainties common to many initiatives in the public and private sectors with regard to funding availability for elements within and outside of the scope of the program, contract acquisition, and prioritization of requirements that would shape the final suite of deliverables.

A statement of work (SOW) approach was used to define the scope of LF 2001/2008 and the data products to be delivered. In essence, the SOW included the development of comprehensive documentation describing the general methodological approach required to develop the suite of LF 2001/2008 intermediate and final products (deliverables). The SOW also included guidelines for quality assurance and quality control procedures, program management and program performance standards, estimates of overall duration, and an independent estimate of cost to the government for the defined scope of work.

A primary element of the SOW was a structured index and definition of work segments and deliverable-scheduled milestones. This structure is referred to as a Work Breakdown Structure (WBS) – also a

Introduction

standard best practice in program planning and management – and is used for effective organization and management of work activities. The SOW document and WBS organization drew upon lessons learned and program management artifacts developed during the completion of the LF National project and the LF 2007 Rapid Refresh project. A summary display of the actual project results in terms of scheduled initiation and completion of project milestones is provided in Figure 2 below. A description of the project milestones (such as GeoAreas and Group A and Group B product segments as outlined in Table 2) is provided in detail in section 1.5 of this report.

Figure 2 – LF 2001/2008 Gantt chart. This is a summary display of the actual results of the start and finish dates of the milestones and segments [such as GeoArea and Group A and Group B products]. These milestones and segments compose the WBS discussed in Section 1.4.

The LF 2001/2008 effort was challenged by external factors such as mandatory work stoppages related to contractual reviews at the USFS and access to a range of qualified vendors through contract vehicles at both DOI component agencies and the USFS. Moreover, evolving management requirements resulted in longer periods of time required to complete processes for conducting full and open competitive bidding and finalizing vendor selection and formal work kickoff. Nonetheless, the use of comprehensive SOW documentation and WBS organization permitted the LF Program to segment certain elements of development work and allocate these elements to vendor organizations that were best qualified and able to complete the LF 2001/2008 work at an optimal combination of cost, quality, and schedule performance.

At the inception of the LF 2001/2008 effort, there was a tight interdependency in scheduling between LF 2001/2008 and the Monitoring Trends in Burn Severity (MTBS) project (Eidenshink et. al 2007). As

Introduction

noted in detail throughout this GeoArea report, LF 2001/2008 used data such as the MTBS mapping products to characterize the landscape changes reflected in LF 2001/2008 data layers. Thus, the structure of LF 2001/2008 production activities as well as product releases were linked to the organization of the original MTBS production schedule, which was segmented by geographic regions across the conterminous United States (CONUS).

1.5 LANDFIRE 2001/2008 Spatial Products

LF 2001/2008 was originally estimated to span 24 months and involve over 500 unique tasks to deliver updated LF data layers. The update was highly dependent upon field data in the form of landscape change polygons and other information regarding landscape conditions. LF partitioned the delivery of the updated LF 2001/2008 products into two segments, "Group A" and "Group B," to facilitate management direction and the fulfillment of user needs. The staggered release of products by GeoArea (Table 1) and grouping of data products (Table 2) was determined to be the most practical approach with respect to scope limitations, cost considerations, and contractual circumstances.

Table 1 – LF 2001/2008 product delivery schedule listing the nine GeoAreas as represented above in Figure 1 and delineating delivery of "Group A" and Group "B" data sets.

Table 1. LF 2001/2008 Schedule		
Geographic Area	Group A	Group B
Southeast	4 th Qtr. 2010	4 th Qtr. 2010
Pacific Northwest	1 st Qtr. 2011	3 rd Qtr. 2011
Pacific Southwest	2 nd Qtr. 2011	3 rd Qtr. 2011
Southwest	2 nd Qtr. 2011	3 rd Qtr. 2011
North Central	2 nd Qtr. 2011	3 rd Qtr. 2011
South Central	3 rd Qtr. 2011	3 rd Qtr. 2011
Northeast	3 rd Qtr. 2011	3 rd Qtr. 2011
Alaska	3 rd Qtr. 2011	4 th Qtr. 2011
Hawaii	3 rd Qtr. 2011	4 th Qtr. 2011

Introduction

Table 2 - LF 2001/2008 list of data products and how they were grouped (Group A and Group B) to facilitate management direction and user needs.

Table 2. LF 2001/2008 Products and Groupings	
Group A	Group B
Fire Behavior Fuel Model 13 (FBFM13)	Biophysical Settings (BpS)
Fire Behavior Fuel Model 40 (FBFM 40)	Vegetation Condition Class (VCC)
Canadian Forest Fire Danger Rating System (CFFDRS) (Alaska Only)	Vegetation Departure Index (VDEP)
Forest Canopy Bulk Density (CBD)	Fire Regime Groups (FRG)
Forest Canopy Base Height (CBH)	Mean Fire Return Interval (MFRI)
Forest Canopy Cover (CC)	Percent Low Severity Fire (PLS)
Forest Canopy Height (CH)	Percent Mixed Severity Fire (PMS)
Fuel Characteristic Classification System	Percent Replacement Severity Fire (PRS)
Fuelbeds (FCCS)	Fuel Loading Models (FLM)
Existing Vegetation Type (EVT)	Succession Classes (SCLASS)
Existing Vegetation Cover (EVC)	
Existing Vegetation Height (EVH)	

2.0 LANDFIRE 2001 and 2008 Methods and Results

2.1 Geographic Area Description

The Southeast (SE) GeoArea consists of eight mapping zones encompassing Florida, Alabama and large portions of Mississippi, Louisiana, Georgia as well as small portions of Arkansas, North Carolina, South Carolina, Tennessee and Texas — approximately 214 million acres. The NLCD mapping zones within the SE GeoArea are listed in Table 3. The ownership of the SE GeoArea is depicted in Figure 3.

Table 3– SE GeoArea mapping zone numbers (see below Figure 3) and titles as labeled by the NLCD program.

Table 3. Southeast GeoArea Mapping Zones	
Mapping Zone	Mapping Zone Name
37	Ouachita Hills
46	Gulf Plains
48	Cumberland Highlands
54	Southern Piedmont
55	Southeastern Coastal Plain
56	Floridian Coastal Plain
98	Mississippi Delta
99	Coastal Gulf Plains

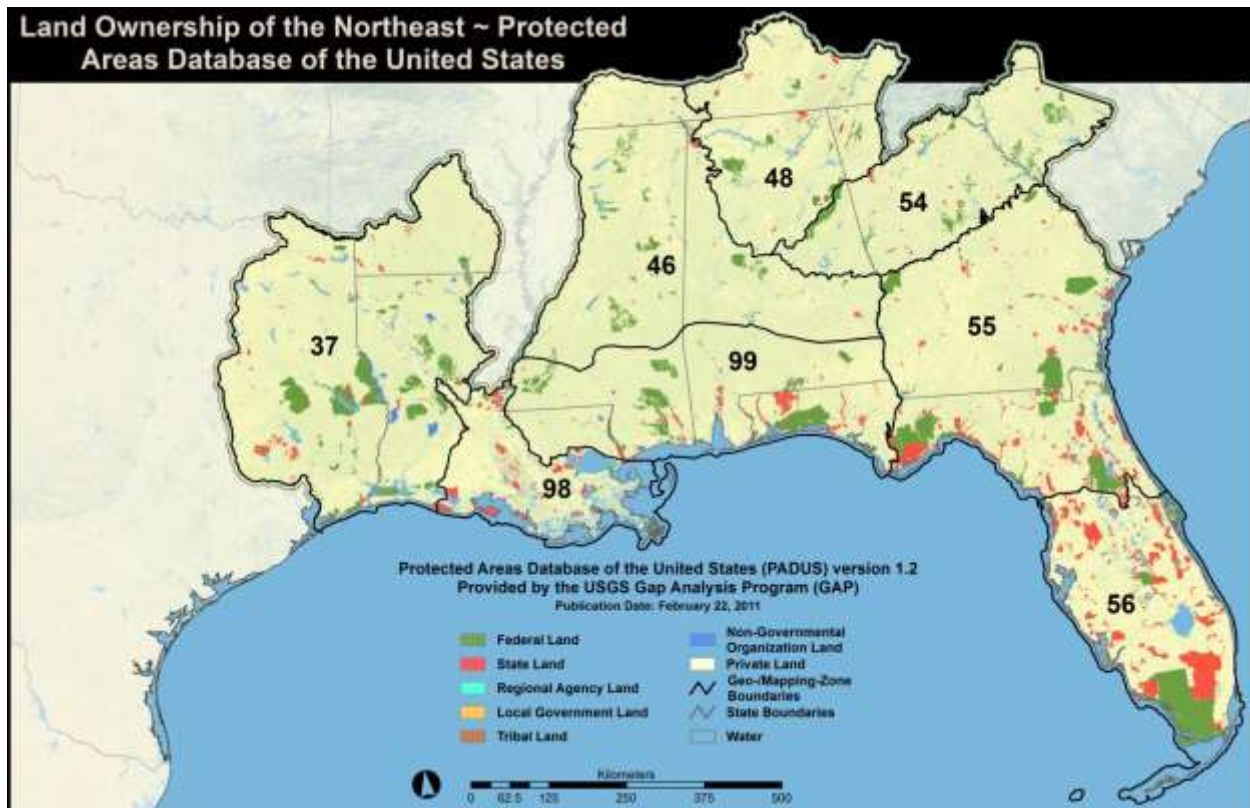

Figure 3 – Land ownership categories for the SE GeoArea.

Within a given GeoArea, land ownership is important because the condition of the landscape, including disturbances, may be a direct result of ownership mission and management activities. A summary of land ownership segmentation across the SE GeoArea is provided in Table 4.

Table 4 – Categories of land ownership, number of acres, and percentages of total GeoArea by category for the LF SE GeoArea.

Table 4. Acreage of Land Ownership Categories for the SE GeoArea.		
Land Ownership	Acres	Percent of GeoArea
Federal Government	11,555,468	5.2
Non-Governmental Organizations/Private	267,028	0.1
Local Government	27,503	0.0
Private	200,680,240	91.1
State Government	7,663,191	3.5
Tribal	29,028	0.0
Total	220,222,458	100.0

2.2 LANDFIRE Reference Database

2.2.1 Product Description

LF 2008 mapping was supported by a large database of field-referenced data. The LANDFIRE Reference Database (LFRDB) includes vegetation and fuel data from over 800,000 geo-referenced sampling units located throughout the United States. These data were amassed from numerous sources, and, in large part, from existing information resources of outside entities, such as the USFS FIA Program, the USGS National Gap Analysis Program (GAP), and State natural heritage programs. Vegetation data drawn from these sources and used by LF include natural community occurrence records, estimates of canopy cover and height per plant taxon, and measurements (such as diameter, height, crown ratio, crown class, and density) of individual trees. Fuel data included biomass estimates of Downed Woody Material (DWM), percent cover and height of shrub and herb layers, and canopy base height estimates. Digital photos of the sampled units, when available, were archived.

A subset of the full suite of field-sampled data used in the production of LF deliverables is available for public access, as stipulated in the 2004 LF Executive Charter. In accordance with agreements between LF and its data contributors, certain proprietary or otherwise sensitive data were removed to create this publically available version of the LFRDB. There are over 275,000 sampling units from 260 different sources located throughout the United States available for public use.

2.2.2 LANDFIRE Reference Database Update Process

The following is a summary of key steps the LF production team conducted to complete the LFRDB component of LF 2001/2008. These methods were subject to revision and update upon the completion of all LF 2001/2008 GeoArea processing.

- Acquired geo-referenced, field-sampled vegetation and fuel data from existing national and local programs - this work required extensive communication with representatives of governmental and non-governmental entities throughout the U.S. and work with FIA staff to draw all relevant data

LANDFIRE 2001 and 2008 Methods and Results

- Maintained a catalog and archive of all acquired data and metadata in their original formats using the existing LF data-catalog template and file structure
- Assessed and prepared acquired data for LF processing - this work required thorough inventorying of acquired geospatial data (in tabular format or as shapefiles, coverages, geodatabases, etc.) with regard to distribution and information content and removal of records with irreconcilable geospatial or information errors/omissions
- Converted relevant/viable data into LF format such that they conformed to standards defined in the data dictionaries for the AutoKey Database to accurately assign Existing Vegetation Type (EVT) to plots that have species composition (species and cover) attributes and LFRDB - this required using intermediate to advanced techniques for relational database management, manipulation and management of point and vector geospatial data, and regular documentation of data-conversion processes and quality-control measures
- Acquired and incorporated into the LFRDB all ancillary spatial data needed for LF production (such as data extracted from LF base and product layers) - this required support from FIA staff and representatives of other entities that provide data with plot locations that must remain confidential
- Derived and incorporated into the LFRDB any attributes necessary for LF production but not acquired as part of the original data sets - this included the derivation of canopy cover and height estimates from FIA tree records, fuel loading estimates from DWM records, un-compacted crown ratios from compacted crown ratios, vegetation map-unit assignments from the Ecological Systems AutoKey, canopy fuel attributes from FuelCalc (Reinhardt, 2006) (a tool to compute surface and canopy fuel loads and characteristics from inventory data), and various attributes from the Forest Vegetation Simulator (FVS; Dixon 2002) and its Fire and Fuels Extension (FFE; Reinhardt and Crookston 2003).
- Checked for information and spatial errors as detailed in the LFRDB Quality Assurance (QA) checklist, and, once removed or appropriately identified, distributed the inaugural LFRDB for LF production
- Maintained and updated the LFRDB after the inaugural posting by archiving relevant LF production information, including results of Quality Assurance / Quality Control (QA/QC) on LFRDB records performed by mapping teams and additional data as requested/permitted by LF mapping teams and leadership

2.2.3 LANDFIRE Reference Database Update Results

Final deliverables for the SE GeoArea consisted of a catalog (spreadsheet) and archive (file system) of all acquired data, an AutoKey Database (Microsoft Access® database) that was developed to quickly and accurately assign EVT to plots that has species composition (species and cover) attributes for the SE GeoArea, a LFRDB (Microsoft Access® database) for the SE GeoArea, and documentation of data conversion processes and QC measures taken during the data-loading stages.

The final LFRDB product for the SE GeoArea resulted in a large number of sampling events derived from various data sources, including the following:

- 78,906 geo-referenced sampling events were contained within the SE LFRDB.
- 66 different sources of data were contributed by Federal, State, and private entities.
- 41% of data were submitted in response to the LF data call (http://www.landfire.gov/participate_refdata.php) and 59% of data were acquired by LF

LANDFIRE 2001 and 2008 Methods and Results

personnel through direct data sharing agreements (USFS FIA), websites such as the NPS Data Store and or agency database systems (USFS- Natural Resource Information System and Field Sampled Vegetation)

- 4,714 Forest Inventory and Analysis (FIA) sampling events were added to the LFRDB for LF 2001/2008 (2,259 were new sampling locations and 2,455 were inventoried)

A substantial amount of vegetation and fuel data were acquired and compiled from many different sources for LF National and LF 2001/2008. The LFRDB team was able to acquire nearly half of the data archived in the SE LFRDB from data sharing agreements, websites, and/or agency databases. Data contributions submitted in response to the data call were also important, accounting for 41% of the sampling events. Major data contributions can be accredited to the USFS and the various state agencies, the rest of the data came from multiple sources. Table 5 shows a breakdown of the data contribution profile for the SE LFRDB.

Table 5 – Data contribution profile for the SE LFRDB.

Table 5 SE LANDFIRE Reference Database Data Contributions		
Data Contribution Profile	Samples	Percent
USFS	25,604	50.5
Multi Agency	21,252	41.9
State	2,236	4.4
Department of Defense	419	0.8
NPS	380	0.7
BLM	367	0.7
Non-Governmental Organizations /Private	320	0.6
Municipal	144	0.3
FWS	0	0
USGS	0	0
BIA	0	0
Total	50,722	100

For LF 2001/2008, the LFRDB team acquired and incorporated additional data into the existing LFRDB to facilitate the improvement and updating of several LF data products. Data provided by FIA contain a complete set of attributes necessary for updating LF products, so efforts were focused on converting and adding these data. During LF 2001/2008, several improvements were made to FIA data processing procedures, including updates to the way forest canopy cover and height metrics were derived and improvements to the LFRDB database schema that allowed for the archiving of repeat measures. There were 4,714 new FIA sampling events added to the SE LFRDB for LF 2001/2008. The SE LFRDB also contains a substantial amount of vegetation data, including information on community occurrence, species composition, vegetation structure, exotic plants, and fuel. Table 6 provides a summary of data types by percent distribution for the SE GeoArea. Community occurrence data include natural community or cover type classifications; species composition data include canopy cover estimates per plant taxon; vegetation structure data include height measurements per life form or plant taxon; exotic plant data include occurrence or cover estimates of exotic plants; and fuel data include composition and characteristics of surface and/or canopy fuel.

Table 6– Percent distribution of data types for SE LFRDB.

Table 6. SE LANDFIRE Reference Database Plot Summary		
Data Type	Samples	Percent *
Community Occurrence Records	26,592	34
Species Composition	30,485	39
Structure	25,267	32
Exotics	21,790	28
Fuels	17,186	22

**Percent occurrence of the listed data types within the LFRDB. The percentages do not total to 100% because a plot may have more than one data type. For example, a plot may have both species composition and fuel data whereas another plot may only have community occurrence records. The 4,714 new FIA plots that were added to the LFRDB provided species composition, structure, and fuel data, but not the other data types listed.*

2.3 Biophysical Settings

2.3.1 Product Description

The Biophysical Settings (BpS) layer represents the vegetation that may have been dominant on the landscape prior to Euro-American settlement and is based on both the biophysical environment and an approximation of the historical disturbance regime. BpS is a refinement of the Environmental Site Potential (ESP), it includes disturbance. In this update, we attempted to incorporate current scientific knowledge regarding the functioning of ecological processes – such as fire – in the centuries preceding non-indigenous human influence. Map units were based on NatureServe's (NS) Ecological Systems classification; a nationally consistent set of mid-scale ecological units (Comer et al. 2003).

LF used these classification units to describe BpS, which differed from their intended use as units of existing vegetation. As used in LF, map unit names represent the natural plant communities that may have been present during the reference period. Each BpS map unit was matched with a model of vegetation succession defined during LF National. The LF BpS concept is similar to the concept of potential natural vegetation groups used in mapping and modeling efforts related to Fire Regime Condition Class (FRCC; Schmidt et al. 2002; www.frcc.gov).

2.3.2 Biophysical Settings Layer Enhancements

One objective for LF 2001/2008 was to simplify the BpS map layer by reclassifying similar ecological systems into BpS Groups. New names were assigned to better reflect the floristic make-up of the grouped systems and to include the appropriate fire regime (I thru V), and a vegetation model was chosen that best represented the grouped systems (Barrett et al. 2010).

This task included a review of all BpS model descriptions and the Model Tracker Database (MTDB) for each mapping zone. MTDB is an Access database application developed by TNC specifically for the LF Program. MTDB contains a very detailed description of every Ecological System mapped by LF, including physiographic characteristics, biological characteristics, and disturbance regime of each system and the individual succession classes within that system, as defined by local experts. In addition, all review comments are contained within MTDB to allow readers to understand the evolution of the models through the development and review processes; LF team members assessed all model transition states, reference conditions, fire-regime groups, and ancillary information to determine similarities between

BpS. At the end of this process, a grouping strategy was proposed and implemented. The final step was the development of a lookup table relating LF National BpS map units and LF 2001/2008 Grouped BpS map units. Redundant and/or similar BpS models were collapsed into one group, and the original LF National BpS codes have corresponding LF 2001/2008 grouped BpS codes.

The process started by establishing a cross-walk between SSURGO Ecological Site polygon data and BpS units. These cross-walk assignments were based primarily on similar dominant vegetation types and additional information such as elevation, ecoregion, and subsection, to distinguish between possible BpS assignments. Next, a map of BpS map units was built and assignments were made to existing SSURGO ecological site polygon data. Based on these data, cross-walked polygons were sampled to develop pseudo plots (a method to address a lack of field data using existing plot and geospatial data) using the ERDAS Imagine© NLCD sampling tool (a remote sensing application for geospatial raster data processing). A map was created for the entire map zone using the models output from See5© using the pseudo plots of BpS map units. The last production step was to combine this new map with the LF National BpS map in order to update BpS in non-forest areas.

2.3.3 Fire Regime Products

Five layers, including Mean Return Interval (MFRI), Percent of Low Severity (PLS) fire, Percent of Mixed Severity (PMS) fire, Percent Replacement Severity (PRS) fire, and Fire Regime Groups (FRG), characterizing modeled historical fire regimes were produced based on the BpS and linkage with the Refresh Model Tracker (RMT). This linkage provides the probability of replacement, mixed, and surface fires. MFRI was calculated as the reciprocal of the sum of these probabilities (which is the probability of fire of any severity), grouped into classes and then combined with the non-vegetated types from the Succession Classes (SCLASS) layer. The PLS, PMS, and PRS layers were calculated respectively as the ratio of the probability of surface, mixed, and replacement fires to the probability of any fire. The FRG (depicted in

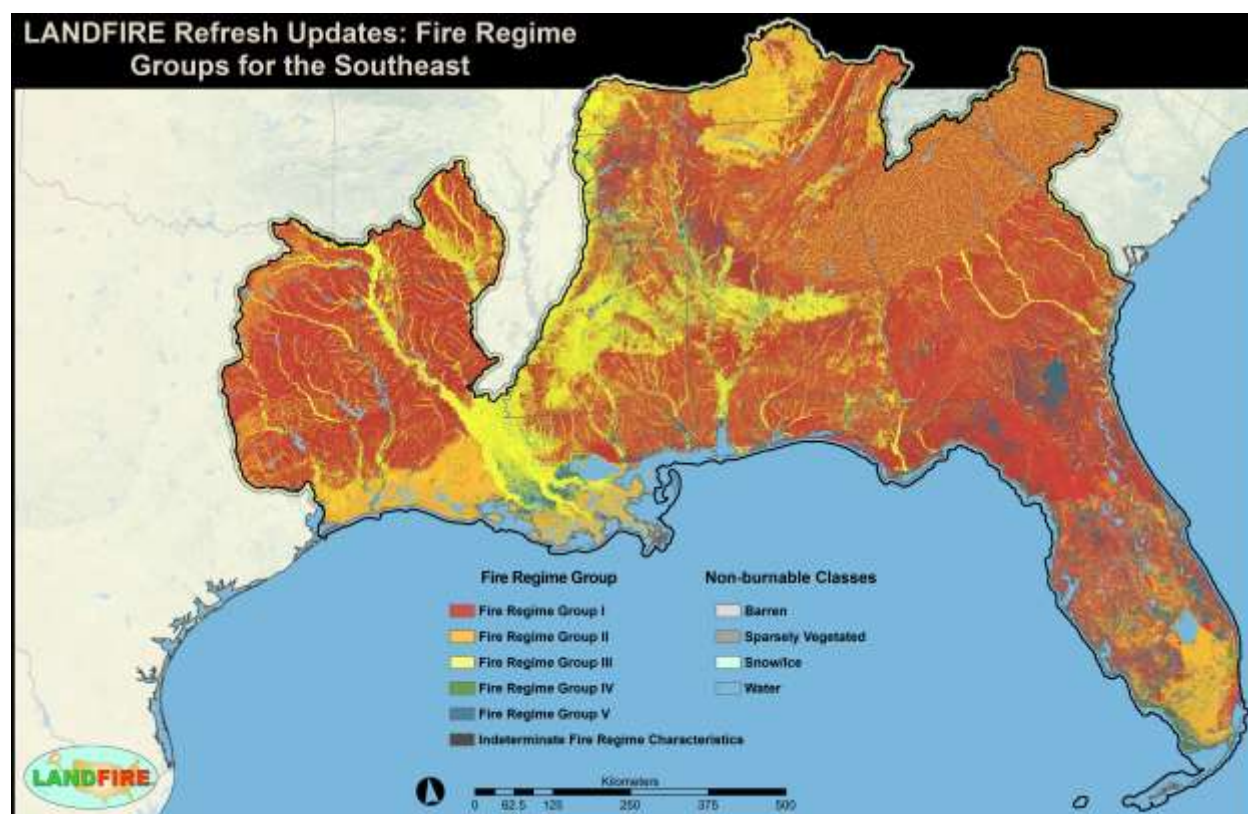

Figure 4) was based on a combination of the MFRI and average fire severity from the FRCC Guidebook (FRCC, 2010), as displayed in Table 7 and Table 8, showing the comparisons between LF National and LF 2001. The vegetation and disturbance dynamics model Vegetation Dynamics Development Tool (VDDT) was used to create the Fire Regime layers for LF 2001 / LF 2008. For LF National the vegetation and disturbance dynamics model LANDSUM (Keane et al, 2006) was used to create the Fire Regime products. This change in methods caused a substantial reduction (99%) in Intermediate Fire Regime Characteristics Group, while FRG III and FRG IV increased 58.3% and 60.9%, respectively.

Table 7– The Fire Regime Groups (FRG) by frequency and Percent Replacement Severity (PRS) for vegetation types within each regime as described in the FRCC Guidebook.

Table 7. Fire Regime Groups, Frequency, and Severity		
Fire Regime Group Name	Frequency (years)	Severity Percent
FRG I	0-35	PRS < 75
FRG II	0-35	PRS ≥ 75
FRG III	35-200	PRS < 75
FRG IV	35-200	PRS ≥ 75
FRG V	200+	All

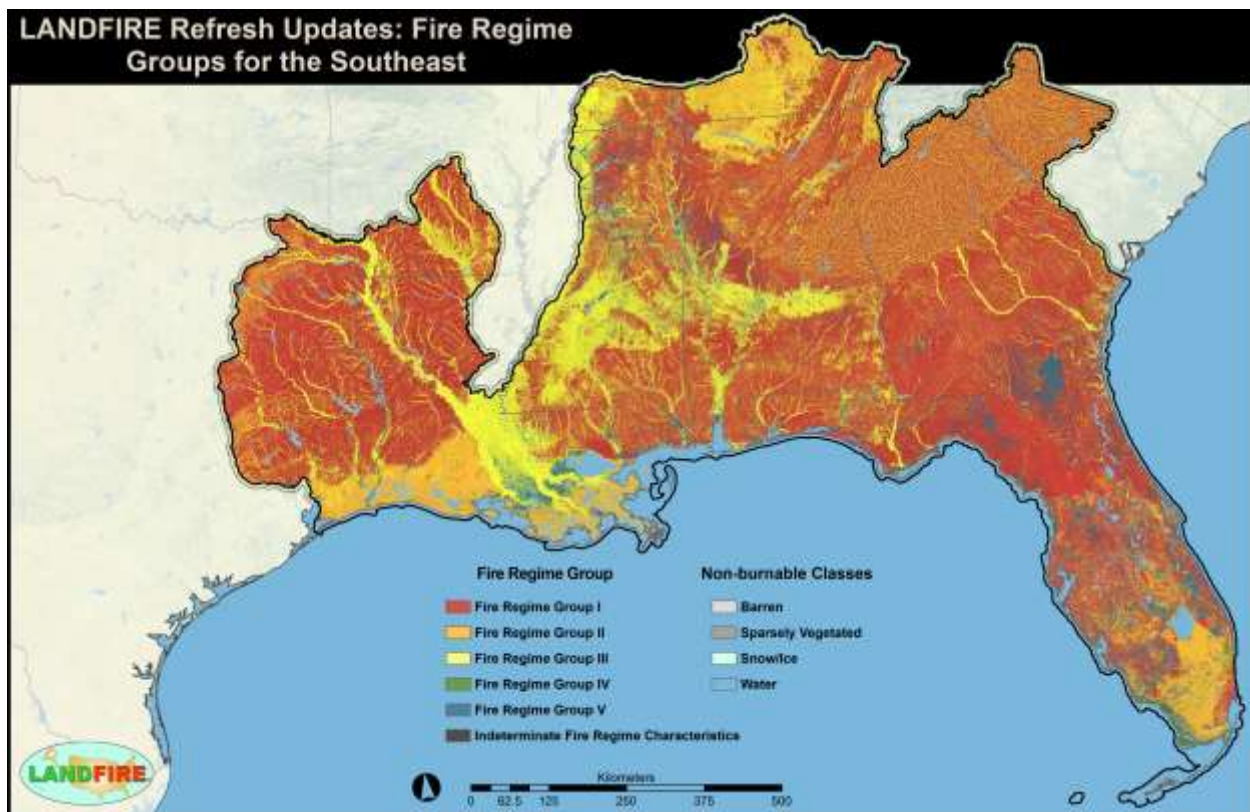

Figure 4 – Map of the SE GeoArea depicting LF Fire Regime Groups in the absence of modern human intervention with possible aboriginal fire use.

Table 8 – Comparison of acreage mapped and percent change by Fire Regime Groups in LF National and LF 2001 versions of LF data.

Fire Regime Group Name	LF National (acres)	LF 2001 (acres)	Percent Change
FRG I	138,070,576	115,554,280	-16.3
FRG II	14,568,056	18,108,205	24.3
FRG III	33,482,641	52,993,728	58.3
FRG IV	323,136	519,984	60.9
FRG V	13,281,773	12,577,152	-5.3
Water	17,070,287	17,267,800	1.2
Snow / Ice	-	-	0.0
Barren	637,951	639,230	0.2
Sparsely Vegetated	6,129	6,129	0.0
Indeterminate Fire Regime Characteristics	26,655	16	-99.9

2.4 Disturbance Mapping

2.4.1 Product Description

LF disturbance data were developed to provide temporal and spatial information related to landscape change for determining vegetation transitions over time and making subsequent updates to LF vegetation, fuel, and other data. Disturbance data include attributes associated with disturbance year,

type, and severity. These data were developed through use of Landsat satellite imagery, local agency derived disturbance polygons, and other ancillary data establishing disturbance grids for each year.

2.4.2 Disturbance Mapping Objectives

Changes in the landscape are pervasive and occur continually. For LF data to remain current, a process was needed to integrate spatial temporal landscape changes into the suite of LF products.

The objective of this process was to map the location, extent, type, and severity of major disturbances for the entire United States. To achieve this objective, several data sets needed to be integrated into one product. Not all types of data were available in all areas. The disturbance mapping process was performed at the LF mapping zone scale.

2.4.3 Disturbance Mapping Process

In accordance with a provision in the LF Charter regarding the directive to regularly update LF products, disturbances to the landscape were identified using a process referred to as Remote Sensing of Landscape Change (RSLC; Vogelmann et al. 2010). The RSLC process includes multiple data sources and processes, including remotely sensed imagery, a spatial database of events, and field assessments. In order to capture disturbance on the landscape, LF worked with the University of Maryland researchers on vegetation (forest) change detection using archived Landsat Time Series Stacks (LTSS; Huang et al. 2009). LF used a vegetation change and tracking algorithm called the Vegetation Change Tracker (VCT; Huang et al. 2010). VCT tracks a vegetation index through a LTSS in order to identify landscape changes. VCT data were developed for each year identifying disturbed areas as well as disturbance severity. As part of the VCT processing, the Normalized Burn Ratio (NBR, Key et al. 2006) was calculated for each input scene. Severity was determined from the Landsat imagery by calculating both the minimum and the maximum NBR value for each pixel for the years 1999 to 2008 from the VCT output. The minimum NBR was then subtracted from the maximum NBR. The result was classified into high, medium, and low severity levels based on a statistical comparison with the MTBS, Burned Area Reflectance Classification (BARC), and Rapid Assessment of Vegetation Condition after Wildfire (RAVG) fire severity data also available for the area.

Since disturbance type, or causality, was not determined in the VCT process, a spatial analysis was conducted comparing the VCT output to buffered (1-kilometer) LF 2008 disturbance event data, which were provided to LF by various local, regional, and national agencies and organizations as part of the LF data contribution opportunity. Disturbance type and year information were included as attributes for each polygon and transferred to the disturbance grids in this process. Data inputs on location of Federal agency lands were included using the Protected Areas Database of the United States (PAD-US; <http://www.protectedlands.net/padus/>). PAD-US is a product of GAP, which shows land management status representing public and private land ownership, and conservation lands that are assigned a conservation status for biodiversity preservation and natural, recreational, or cultural uses. PAD-US and its "GAP Status" attribute were used to inform causality for disturbances outside of disturbance event polygons. While not identifying a precise type of disturbance, this analysis provides information useful for narrowing down the types of disturbance that would be expected to occur in a given location.

LANDFIRE 2001 and 2008 Methods and Results

Wildland fire disturbance data are developed through a multistep process. Inputs to this process include fire mapping data obtained from the MTBS, BARC, and RAVG fire mapping efforts. These three data sets were merged together to map the extent and severity of wildland fires.

Subsequently, all disturbance types were processed, creating 10 disturbance grids, one for each year from 1999 to 2008. Each grid was attributed with year, disturbance type (if known, otherwise a description of possible types), severity, and the data sources used to create the data.

In addition to these yearly disturbance grids, an integrated composite of vegetation disturbance data was developed according to the following priorities, in order of importance: time since disturbance, type, and severity for the entire 10-year period. The disturbance types included the following:

- Recent fire activity (1999 through 2008)
- Mechanical treatments that do not remove material from the site (Mechanical Add)
- Mechanical treatments that do remove material from the site (Mechanical Remove)
- Wind disturbance
- Insect and disease

The severity of the disturbance was described as high, moderate, or low. Following are the general guidelines for categorizing:

- High = >75% of above-ground vegetation mortality
- Moderate = 25 to 75% above-ground vegetation mortality
- Low = <25% above-ground vegetation mortality

Time since disturbance was separated into three categories (or time steps), including the following:

- 0-3 years post disturbance
- 4-10 years post disturbance

2.4.4 Disturbance Mapping Results

Disturbance categories were mapped and tabulated for the entire SE GeoArea (Table 9). Disturbed areas are depicted in Figure 5. Across all lands, 8.6 % of the SE GeoArea was mapped as disturbed from 1999 to 2008, leaving 91.4 % undisturbed. On Federal lands, 25.9 % of the GeoArea was mapped as disturbed, leaving 74.1 % undisturbed. We recognize that certain types of disturbances are missed in the mapping process, particularly subtle changes such as decline of certain forest cover types affected by insects or disease. Table 10 through Table 14 provide a detailed listing of mapped disturbance by type on all lands and Federal lands.

Table 9 –Total mapped disturbances area and percent by land ownership category for the SE GeoArea.

Table 9. Disturbance Acreage by Land Ownership			
Land Ownership	Category	Acres	Percent Ownership
All Lands	No Disturbance	198,994,170	91.4
All Lands	All Disturbances	18,672,352	8.6
Federal Lands	No Disturbance	7,890,449	74.1
Federal Lands	All Disturbances	2,754,764	25.9

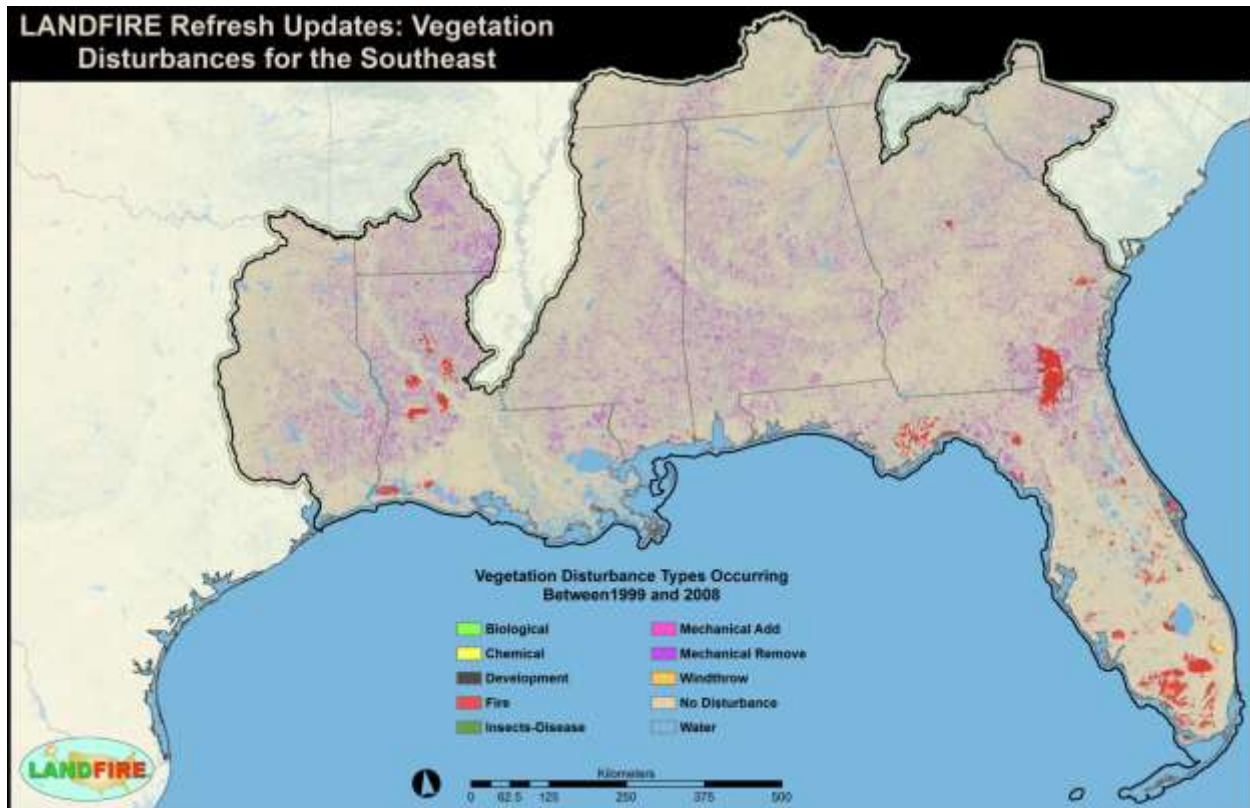

Figure 5 – Map of vegetation disturbance types (fire, mechanical, etc.) mapped for the SE GeoArea from 1999 to 2008.

Table 10 – Number of acres mapped as affected by fire disturbance for severity classes of low, moderate, and high with the period of years since disturbance between All Lands and Federal Land ownership for the SE GeoArea.

Table 10. Area Affected by Fire Disturbance				
Land Ownership	Category	Severity	Time Since Disturbance	Acres
All Lands	Fire	Low	One Year	793,037
All Lands	Fire	Low	Two to Five Years	1,431,509
All Lands	Fire	Low	Six to Ten Years	582,216
All Lands	Fire	Moderate	One Year	207,077
All Lands	Fire	Moderate	Two to Five Years	708,659
All Lands	Fire	Moderate	Six to Ten Years	279,406
All Lands	Fire	High	One Year	44,049
All Lands	Fire	High	Two to Five Years	167,049
All Lands	Fire	High	Six to Ten Years	61,972
Federal Lands	Fire	Low	One Year	490,772
Federal Lands	Fire	Low	Two to Five Years	779,500
Federal Lands	Fire	Low	Six to Ten Years	142,781
Federal Lands	Fire	Moderate	One Year	174,897
Federal Lands	Fire	Moderate	Two to Five Years	565,146
Federal Lands	Fire	Moderate	Six to Ten Years	194,041
Federal Lands	Fire	High	One Year	37,477
Federal Lands	Fire	High	Two to Five Years	108,005
Federal Lands	Fire	High	Six to Ten Years	10,861

Table 11 – Number of acres mapped as affected by the Mechanical Add disturbance by severity classes of low, moderate, and high with the period of years since disturbance between All Lands and Federal Land ownership for the SE GeoArea.

Table 11. Area Affected by Mechanical Add Disturbance				
Land Ownership	Category	Severity	Time Since Disturbance	Acres
All Lands	Mechanical Add	Low	One Year	5,618
All Lands	Mechanical Add	Low	Two to Five Years	2,744
All Lands	Mechanical Add	Low	Six to Ten Years	1,156
All Lands	Mechanical Add	Moderate	One Year	9,567
All Lands	Mechanical Add	Moderate	Two to Five Years	10,014
All Lands	Mechanical Add	Moderate	Six to Ten Years	5,809
All Lands	Mechanical Add	High	One Year	580
All Lands	Mechanical Add	High	Two to Five Years	1,721
All Lands	Mechanical Add	High	Six to Ten Years	3,029
Federal Lands	Mechanical Add	Low	One Year	5,543
Federal Lands	Mechanical Add	Low	Two to Five Years	2,727
Federal Lands	Mechanical Add	Low	Six to Ten Years	1,151
Federal Lands	Mechanical Add	Moderate	One Year	9,296
Federal Lands	Mechanical Add	Moderate	Two to Five Years	9,756
Federal Lands	Mechanical Add	Moderate	Six to Ten Years	5,656
Federal Lands	Mechanical Add	High	One Year	533
Federal Lands	Mechanical Add	High	Two to Five Years	1,468
Federal Lands	Mechanical Add	High	Six to Ten Years	2,622

Table 12 – Number of acres mapped as affected by the Mechanical Remove disturbance by severity of classes of low, moderate, and high with the period of years since disturbance between All Lands and Federal Land ownership for the SE GeoArea.

Table 12. Area Affected by Mechanical Remove Disturbance				
Land Ownership	Category	Severity	Time Since Disturbance	Acres
All Lands	Mechanical Remove	Low	One Year	11,686
All Lands	Mechanical Remove	Low	Two to Five Years	32,514
All Lands	Mechanical Remove	Low	Six to Ten Years	34,906
All Lands	Mechanical Remove	Moderate	One Year	775,183
All Lands	Mechanical Remove	Moderate	Two to Five Years	2,048,932
All Lands	Mechanical Remove	Moderate	Six to Ten Years	2,633,061
All Lands	Mechanical Remove	High	One Year	983,022
All Lands	Mechanical Remove	High	Two to Five Years	3,293,377
All Lands	Mechanical Remove	High	Six to Ten Years	4,490,024
Federal Lands	Mechanical Remove	Low	One Year	1,106
Federal Lands	Mechanical Remove	Low	Two to Five Years	1,487
Federal Lands	Mechanical Remove	Low	Six to Ten Years	2,263
Federal Lands	Mechanical Remove	Moderate	One Year	16,247
Federal Lands	Mechanical Remove	Moderate	Two to Five Years	48,702
Federal Lands	Mechanical Remove	Moderate	Six to Ten Years	39,940
Federal Lands	Mechanical Remove	High	One Year	12,552
Federal Lands	Mechanical Remove	High	Two to Five Years	38,880
Federal Lands	Mechanical Remove	High	Six to Ten Years	46,088

2.5 Existing Vegetation

2.5.1 Product Description

The existing vegetation layers for each LF mapping zone include: EVT, Existing Vegetation Cover (EVC), and Existing Vegetation Height (EVH). All three layers were originally mapped using predictive landscape models based on extensive field-reference data, satellite imagery, biophysical gradient predictor layers, and classification and regression trees. Various parts of these existing vegetation layers were edited and refined as part of LF 2001/2008. The EVT layer represents the current dominant vegetation using map units derived from NatureServe's (NS) Ecological Systems vegetation classification. The EVC layer represents the average percent cover of existing vegetation for a 30 meter grid cell. The EVH layer represents the average height of the dominant/co-dominant vegetation for a 30 meter grid cell.

2.5.2 LF 2001: Enhancements to Existing Vegetation Products

With the release of LF National data products, several areas in the EVT layer were identified for improvement. In 2009, leadership direction and funding were provided to implement these improvements for the CONUS. In Table 15 through Table 31 and in Table 34 and Table 35 of this report, comparisons are made between the LF National data product and the LF 2001 product and the LF 2001 and the LF 2008 updated products. It is important to note that in the majority of cases, the percent changes between the National and LF 2001/2008 are a result of classification and product differences and not actual changes on the ground. LF staff developed a series of steps to improve LF National vegetation data. In addition, problems with the LF National Forest Canopy Cover (CC) documented by Scott (2008) needed to be addressed. Generally, CC values were too high, accuracy was relatively low, and seam lines sometimes existed within mapping zones or between adjacent mapping zones. New metrics of tree cover and tree height were developed using tree plot data (Toney et al. 2009) and new tree cover and height maps were developed. Also, the amount of barren areas mapped in the EVT was adjusted by a series of processes, including rectifying barren areas with NLCD, removing water on

slopes, classification of surface mines, and reclassifying areas depicted as barren in the fuel layers that were not classified as barren in the LF National EVT layer.

2.5.2a Enhancements to Existing Vegetation Type

As part of the enhancements, revisions were made to the international boundaries to coincide with existing data sets. For the United States/Canada border, data from the International Boundary Commission (<http://www.internationalboundarycommission.org/boundary.html>) were incorporated. For the United States/Mexico border, data from the International Boundary and Water Commission (<http://www.ibwc.state.gov/>) and the U.S. - Mexico Border Environmental Health Initiative (<http://borderhealth.cr.usgs.gov/projectindex.html>) were incorporated. Gaps in LF data were filled with either LF National existing vegetation from the 3-km buffer developed around each mapping zone or NLCD2001 land cover data.

At the beginning of LF National, the NLCD2001 land cover layer was partially complete, creating inconsistencies in land cover classes between the final NLCD2001 land cover and LF National layers. Improvements to the LF existing vegetation layers attempted to synchronize these two layers. First, natural land cover classes were reclassified to anthropogenic land cover classes based on the NLCD2001 land cover product. Where NLCD2001 was classified as a natural land cover class and LF layers were classed anthropogenic land cover, LF data were reclassified to the most dominant natural land cover class. Also in this process, herbaceous wetland vegetation types from the NLCD2001 product were mapped to the LF National EVT product. Riparian EVTs mapped in LF National that coincided with stream networks one pixel wide were removed from the existing vegetation layers. The effects of these changes are depicted in Table 19.

To address potentially burnable agricultural classes, information from the National Agricultural Statistics Survey (NASS; <http://www.nass.usda.gov/>) and PAD-US was incorporated into the LF 2001 EVT layer. On non-Federal lands where NASS and NLCD2001 agricultural classes were coincident, NASS classification took precedence. Where NASS and NLCD2001 agricultural classes were not coincident, both classes were retained. Agricultural classes were removed on most Federal lands and assigned a natural EVT. Most revised agricultural classes resulted in burnable fuel models and are depicted in Table 15 and Table 16. This change in process development in this product created new EVT class names, resulting in 100% change for some classes.

In order to address potentially burnable urban the NLCD2001 low and medium intensity urban classes were modeled to “developed” NLCD natural vegetation classes. Roads were reintroduced using the National Transportation Statistics (<http://www.bts.gov/>) layer and filtered by adjacent life form. If canopy fire spread was possible, the roads were removed. NLCD2001 classes 21 and 22 received a burnable fuel model, while classes 23, 24, and 25 remained non-burnable. The effects of these changes are depicted in Table 17 and Table 18. This change in process development in this product created new EVT class names, resulting in 100% change for some classes.

In Figure 6, LF 2001 EVT is depicted. The EVTs are grouped by National Vegetation Classification Standard (NVCS) Subclass to assist with interpretation.

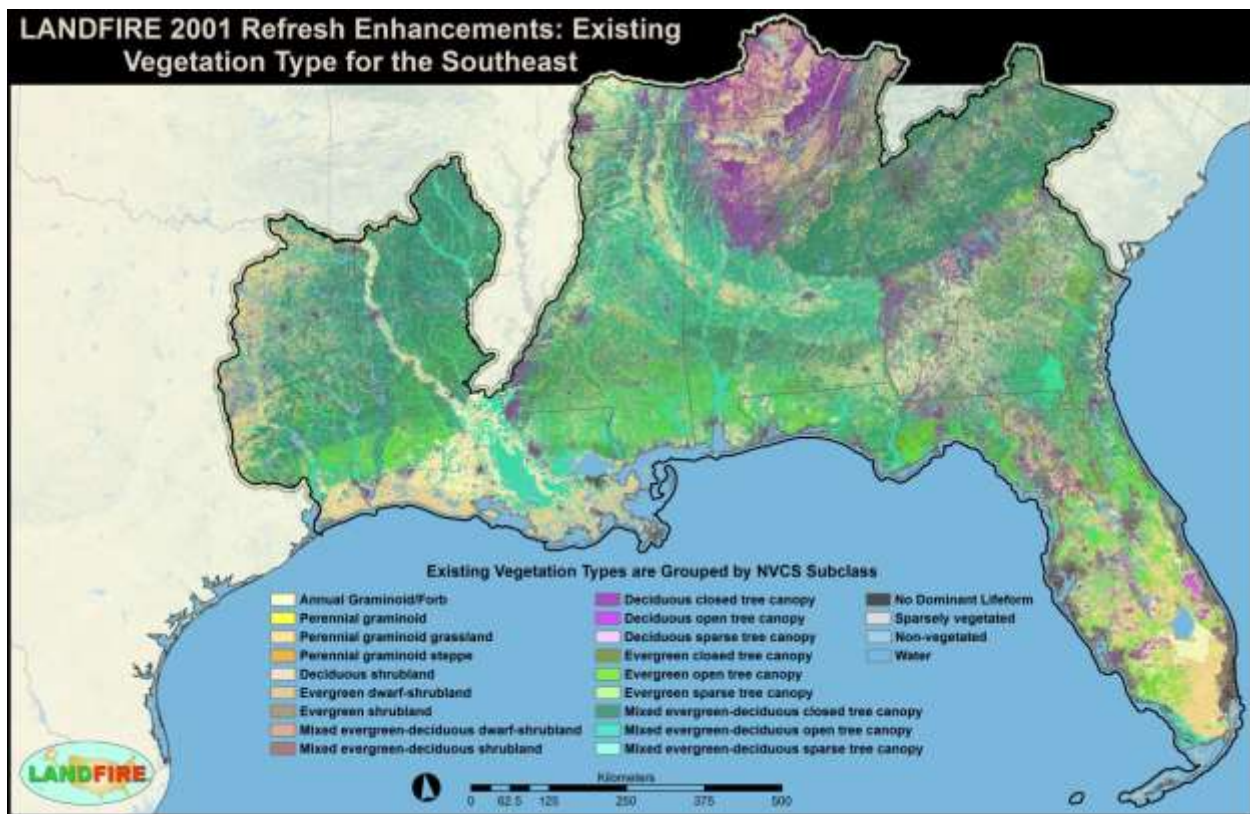

Figure 6 – Map of Existing Vegetation Type layer that was enhanced as part of the LF 2001 updates by incorporating user feedback and additional data.

2.5.2b Enhancements to Existing Vegetation Cover

EVC was updated for forested areas using several dates of Landsat imagery and derived layers. Landsat scenes from leaf-off, leaf-on, and spring dates, along with tasseled-cap images, and texture images derived from tasseled-cap images of the three image dates were used. Elevation Derivatives for National Applications (EDNA) data products were used, including Digital Elevation Model and derivatives (slope and aspect). EDNA is a multi-layered database derived from a version of the National Elevation Dataset, which has been hydrologically conditioned for improved hydrologic flow representation (<http://edna.usgs.gov/>).

Training sites derived from FIA plot records were classified to tree canopy cover using a FIA stem-mapping algorithm (Toney et al. 2009). Plot data records were filtered based on FIA disturbance attributes and location-specific Landsat image dates to obtain tree canopy cover training sites. Some plots were omitted from the training set if they had substantial disturbances (such as cutting, fire, or wind) recorded after the most recent location-specific image date in the multi-temporal Landsat mosaics.

Regression tree modeling was conducted using Rulequest's® Cubist program. Spatial data layers were then rebuilt to produce the final geospatial layer of CC. Layers were visually checked for seam lines and presence of clouds and other issues or artifacts in the imagery; these were addressed by eliminating problem source data or by making localized revisions to the maps.

The desired outcome of this analysis was to map a statistical distribution of CC values consistent with the distribution expected for spatial wildland fire analysis (Scott and Reinhardt 2005; Stratton 2006). CC rarely exceeds 70 % in western U.S. forest types, but is somewhat higher in the multi-storied forests of the eastern U.S. The distribution of stem-mapped FIA plot canopy cover was generally consistent with the distribution as evaluated in the wildland fire behavior models. The modeling enhancements based on this FIA approach have improved the data with earlier problems of CC values being too high. The improved CC maps were combined with the existing shrub and herb components to produce the final

improved EVC layer. In Figure 7, a map depicts EVC and the effects of the process changes are depicted in Table 22.

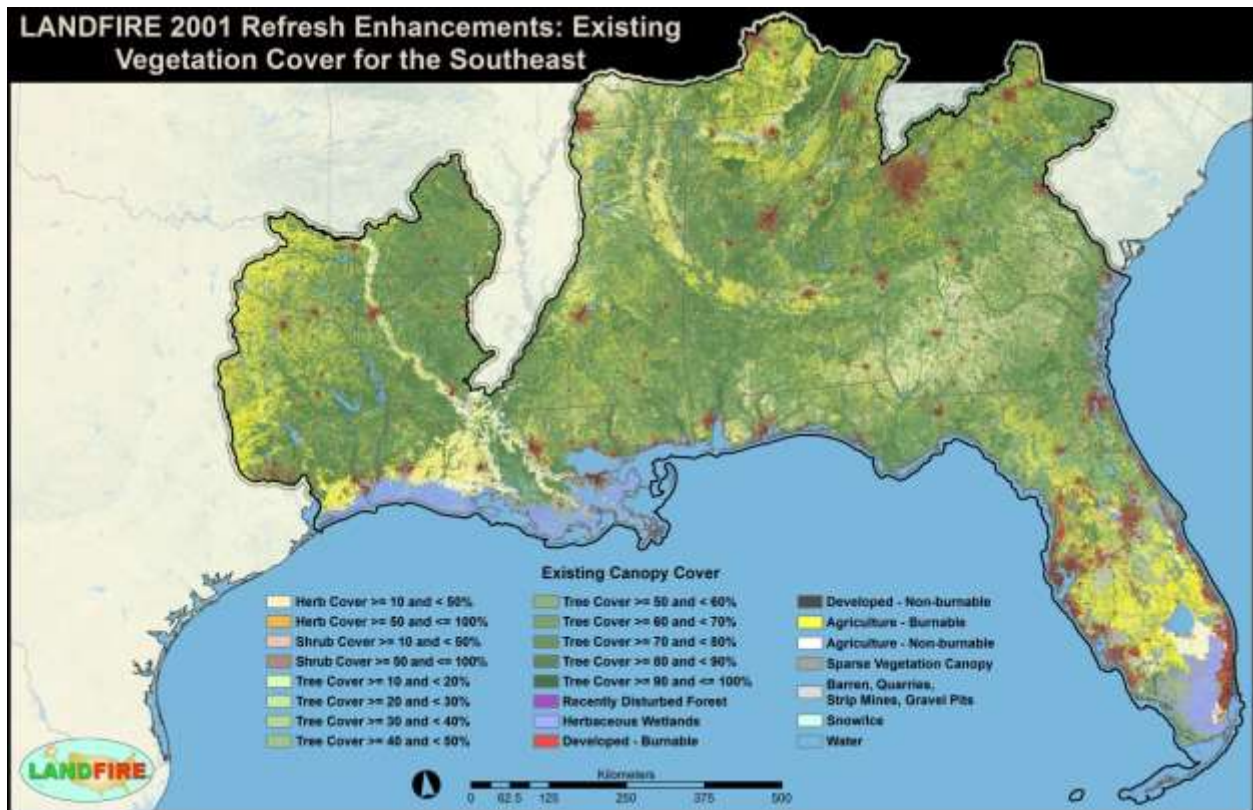

Figure 7 – Map of Existing Vegetation Cover layer that was enhanced as part of the LF 2001 update by incorporating user feedback and additional data.

Table 22 – Existing Vegetation Cover: Forest Canopy Cover – Comparison between LF National and Refresh 2001 tree cover classes and percent change in the SE GeoArea by ownership categories.

Table 22. Tree Cover Comparison				
Land Ownership	Percent Tree Cover	LF National (acres)	LF 2001 (acres)	Percent Change
All Lands	>= 10 and < 20	3,591,482.4	1,542,394.7	-57.1

Federal Lands	>= 90 and <= 100	2,031,791.2	37,750.7	-98.1

2.5.2c Enhancements to Existing Vegetation Height

The EVH improvement and enhancement process focused on Forest Canopy Height (CH). The CH remapping relied on values derived from FIA plot data using a stand height algorithm. FIA plots falling within a given map zone (including a 3-km buffer) were included. The buffer was extended outwards for zones that had very few plots within them in an attempt to expand the data pool. Geospatial data used in the modeling of CH included Landsat imagery, topography data, and a basal area weighted canopy height product developed by Kelldorfer et al. (2004) using Shuttle Radar Topography Mission data. For each zone, predictor variables determining CH were identified and used to build a regression tree model. Continuous values of CH were then mapped without regard to underlying life form for each mapping zone in the GeoArea. The final step grouped the predicted continuous CH values into LF EVH classes and merged these with the shrub and herbaceous EVH components from LF National to create the new LF 2001 EVH layer. LF 2001 EVH is depicted in Figure 8 and the effects of these process changes are listed in Table 23.

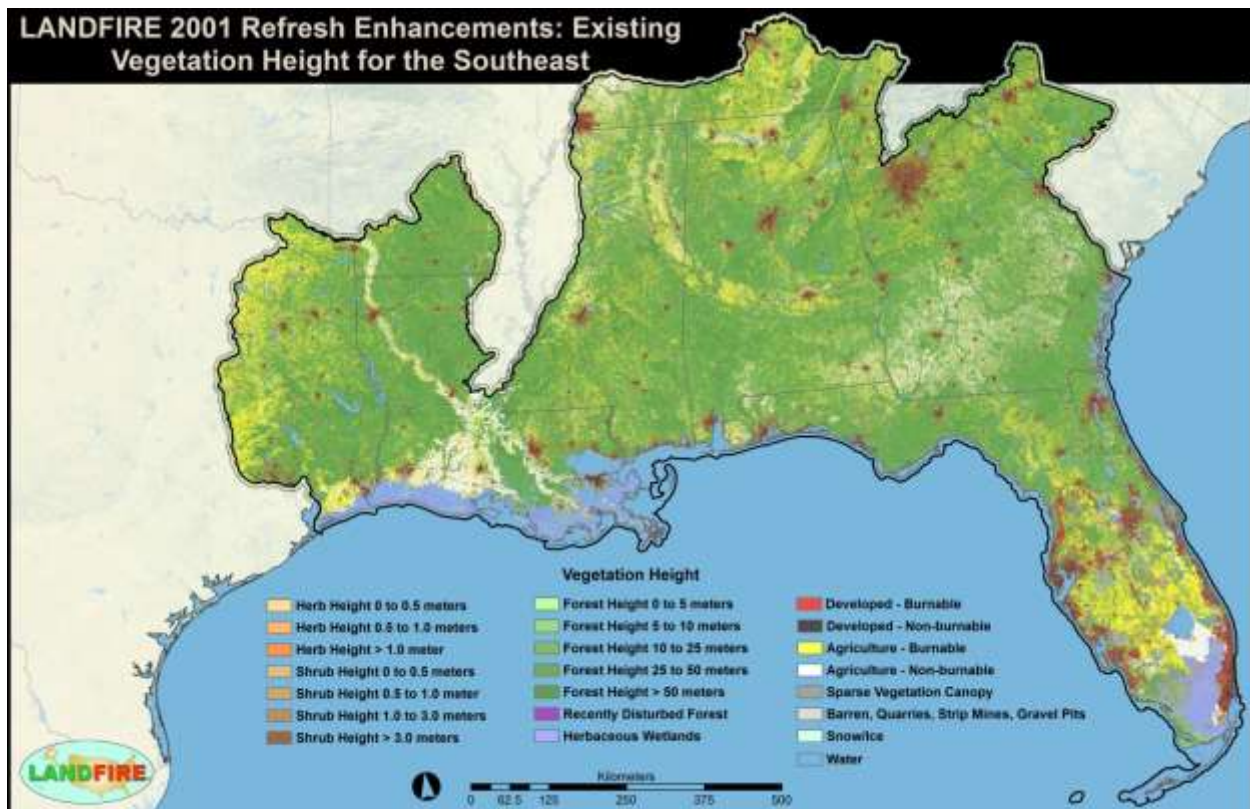

Figure 8 – Map of Existing Vegetation Height layer that was enhanced as part of the LF 2001 update by incorporating user feedback and additional data.

Table 23 – Acreage of LF Forest Canopy Height categories and percent change in the SE GeoArea by ownership categories.

Table 23. Tree Height Comparison				
Land Ownership	Height (m)	LF National (acres)	LF 2001 (acres)	Percent Change
All Lands	0 to 5	4,949,664.9	618,102.9	-87.5
All Lands	5 to 10	15,334,783.1	9,956,333.9	-35.1
All Lands	10 to 25	105,639,269.6	100,620,951.6	-4.8
All Lands	25 to 50	482,360.3	14,385,095.3	2,882.2
Federal Lands	0 to 5	411,297.3	57,337.2	-86.1
Federal Lands	5 to 10	661,159.2	721,547.2	9.1
Federal Lands	10 to 25	6,687,964.5	5,656,766.7	-15.4
Federal Lands	25 to 50	74,839.7	1,417,289.8	1,793.8

2.5.3 LANDFIRE 2008: Updates to Existing Vegetation Products

The primary focus for updating the LF existing vegetation layers was to characterize changes in vegetation attributes in areas that had disturbance activities from 1999 - 2008. Additionally, the update included changes in vegetation attributes within these disturbance areas due to tree growth and regeneration.

As discussed in section 2.4, disturbance mapping for LF 2008 was the result of several efforts that included data derived in part from remotely sensed land change methods, MTBS, and the LF 2001/2008 events data contribution opportunity. Data contributed from various State, Federal and local sources were paired with remote sensing techniques to produce disturbance maps identifying disturbance type, location, and severity.

The spatial layers created by disturbance mapping identified the areas where EVT, EVC, and EVH needed to be transitioned into new vegetation classes. Forest transitions were modeled using FVS and FFE. Non-forest transitions were assigned using information from a variety of sources from the literature. A Vegetation Transition Data Base (VTDB) was developed for each GeoArea to generate vegetation transitions that were assigned to each EVT, EVH, and EVC for every disturbance and its severity. The VTDB was used to perform an update query that modified the existing attribute tables associated with EVT, EVH, and EVC layers.

2.5.3a Updates to Existing Vegetation Type

Information from a variety of sources was used to inform vegetation transition assignments. A series of tables created in a VTDB were used to update attribute tables for the LF 2008 EVT layer.

In forested EVTs, low and moderate severity disturbance did not change EVT. Stand-replacing events such as high severity fire and timber harvests in forested EVTs were transitioned to an herbaceous or shrubland EVT with a cover and height appropriate for an early seral expression of that EVT and for that geographic location. It was assumed that some herbaceous and shrub communities would transition to forested communities. These sites were typically within formerly forested communities where non-forested EVTs occurred in areas of older, not recent disturbance. In these situations, shrub and herbaceous communities were transitioned to an appropriate forested EVT. Relationships between ESP and these shrub and herbaceous communities were used to predict the new forested EVT at a particular

LANDFIRE 2001 and 2008 Methods and Results

site. Successional class A in the Vegetation Dynamics Development Tool (VDDT) models (ESSA 2005) informed cover and height estimations for 2008 EVT assignments and 2008 cover and height transitions.

In shrub EVTs, all fire severities were considered stand-replacing, so all burned non-forested polygons were replaced by an herbaceous EVT that would be found in that area. Chemical treatments were assumed to be performed on exotic species, so a native herbaceous community for that local or regional area replaced the introduced EVT. Mechanical treatments were treated similarly to fire disturbances and transitioned to an herbaceous community. Introduced annual grasses replaced some shrub-dominated EVTs in lowland areas (for example, Western U.S. Great Basin and Columbia Plateau shrubland EVTs). In herbaceous EVTs, disturbed areas were not transitioned to different EVTs due to the fact that these communities rapidly reestablish themselves after disturbance. In Figure 9, LF 2008 EVT is depicted. The EVTs are grouped by National Vegetation Classification Standard (NVCS) Subclass to assist with interpretation.

Agricultural mapping for LF 2001 included the use of NASS Cropland Data Layer (CDL) to expand the number of agricultural classes to improve fuel assignments. The USDA NASS Cropland Data Layer (CDL) is a raster, geo-referenced, crop-specific land cover data layer with a ground resolution of 30 meters. The CDL is produced using satellite imagery during each growing season. The purpose of the CDL Program is to use satellite imagery to (1) provide acreage estimates to the Agricultural Statistics Board for the state's major commodities and (2) produce digital, crop-specific, categorized geo-referenced output products. In LF 2001, CDL classes were used only within areas mapped as agriculture in LF National (based on NLCD2001 agriculture mapping). In LF 2008, the use of CDL was not confined to NLCD2001 agricultural mapping and was additive to the NLCD2001 product. This resulted in significant increases in the mapping of certain agricultural classes, an issue compounded by NASS' assignment of certain anthropogenic grasslands types as agriculture.

2.5.3c Updates to Existing Vegetation Height

Transitions in the forested component of EVH due to disturbance and succession were modeled using FVS/FFE. These transitions were applied to the LF 2001 CH layer to create the LF 2008 CH layer (Figure 11). Using FIA plot data for forested vegetation types, the model was calibrated to disturb the sites with a variety of disturbance types and severities.

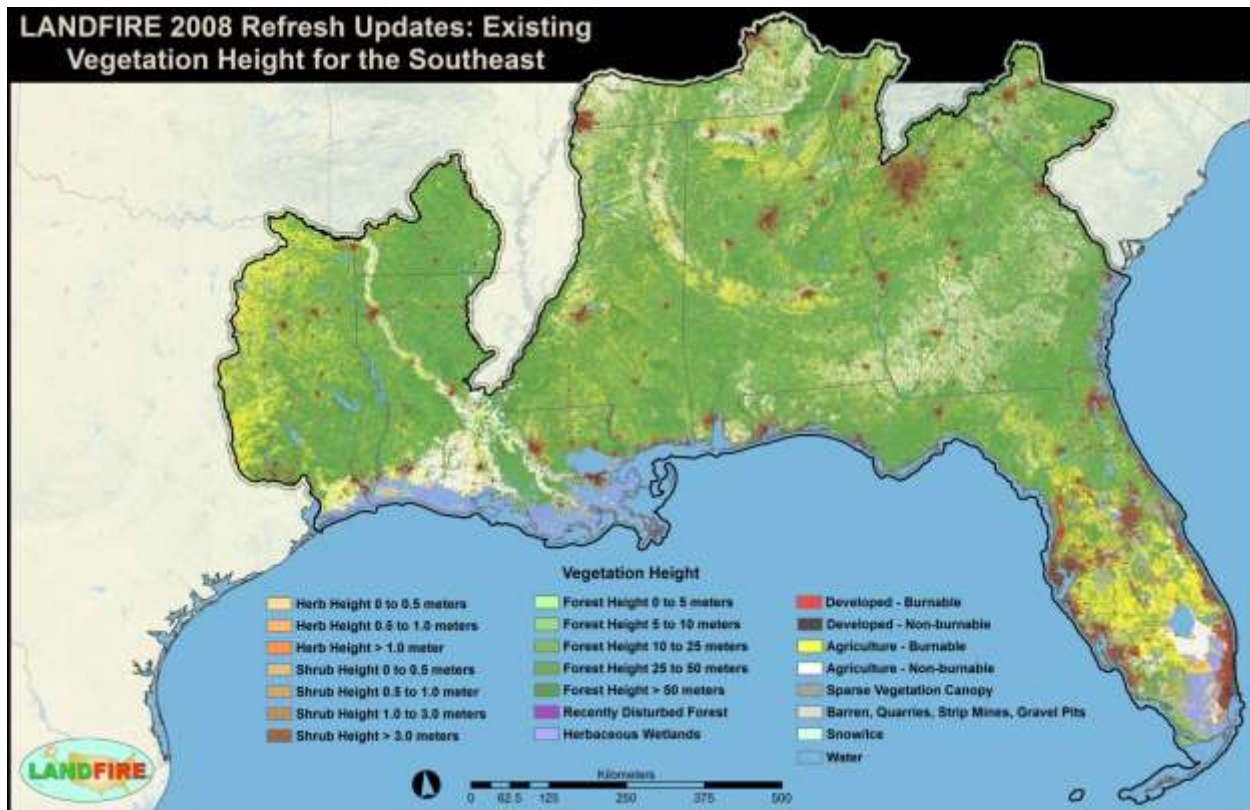

Figure 11 – Map of Existing Vegetation Height for the SE GeoArea accounting for vegetation changes from disturbances for 1999 - 2008.

Table 29 – Existing Vegetation Height: Tree Height – Comparison between LF 2001 and 2008 Refresh.

Table 29. Tree Height Comparison				
Land Ownership	Height (m)	LF 2001 (acres)	LF 2008 (acres)	Percent Change
All Lands	0 to 5	618,102.9	1,527,228.5	147.1
All Lands	5 to 10	9,956,333.9	7,973,566.0	-19.9
All Lands	10 to 25	100,620,951.6	99,934,687.7	-0.7

Federal Lands	25 to 50	1,417,289.8	1,468,013.8	3.6

2.6 Fire Behavior

2.6.1 Product Description

The LF fuels data describe the composition and characteristics of both surface and canopy fuel. Geospatial products include Fire Behavior Fuel Model 13 (FBFM13; Anderson, 1982), Fire Behavior Fuel Model 40 (FBFM40; Scott and Burgan, 2005), and the Canadian Forest Fire Danger Rating System (CFFDRS; Stocks et al. 1989), Forest Canopy Bulk Density (CBD), Forest Canopy Base Height (CBH), CC, and CH. The landscape file (.LCP) is the data format required for many fire behavior and effects models and was provided as well. These data can be implemented within models to predict wildland fire behavior and fire effects and are useful for strategic fuel treatment prioritization and tactical assessment of fire behavior and effects.

The primary effect of the improvements to the LF National layer, from a fuel and fire behavior perspective, was an enhanced mapping of EVC and EVH. The re-mapped EVC had the most effect on the fuel grids and their subsequent modeled fire behavior characteristics.

2.6.2 LF 2001 Enhancements to Fire Behavior Products

With the release of LF National, the user community alerted the LF team to some problems with the fire behavior and fuel attributes. The LF 2001 data set was created in part to address a number of these issues by instilling methods of calculating fuel attributes based on new EVC and EVH layers. Some of the issues raised were:

- CBH was too high for many of the forested systems
- CBD was too low for many of the forested systems
- The combination of FBFM 40/13 and the CBH layers did not produce the expected fire behavior characteristics
- High CC caused high wind reduction factor

2.6.2a Enhancements to Surface Fuel

The FBFM40/13 fuel model grids for LF National were based on input provided by regional fuel specialists and the LF fuel team. Surface fuel models were dependent upon the type of vegetation described in the EVT layer, the amount of cover and/or closure in the overstory of the vegetation from EVC, and the height of the vegetation expressed by EVH. Fuel model assignments were given break points of EVC and EVH for each EVT to determine the fuel model. For instance, in a forested EVT in an open condition, a grass or shrub model would be used in the low cover rule set to describe the surface fuel. As the stand closed in the higher EVC classes, a timber understory or timber litter model would often be used in a subsequent rule set.

With the inclusion of a new method to determine EVC and EVH, the rule sets that were created for FBFM40/13 at workshops with regional specialists remained the same, but the pixels on the map covered by a particular rule set shifted depending on the change in cover and/or height of the vegetation. Although herbaceous, shrub, and tree life forms were mapped in the EVC and EVH products, the forested or treed EVTs were affected by the new approach in cover and height. The change in number and location of pixels that changed fuel models was dependent on the change in cover or height in the forested EVTs.

LANDFIRE 2001 and 2008 Methods and Results

Many acres in the higher CC classes in LF National were remapped in LF 2001 to lower CC classes, affecting the amount of acres in the various surface fuel assignments (depicted in Table 28 and Table 29). The height classes were also affected, which caused acres to shift from the 0-5 meter class into the higher height classes – often resulting in a change of surface fuel assignment. Some rule sets seemed like duplicates, but were in fact different rules, depending on whether the forested vegetation was available for crown fire.

Upon preliminary completion of the layers and before final processing of LF 2001 fuel layers, all the surface fuel models for CONUS were assembled by EVT and Map Zone (Figure 12). This compilation was done to identify those areas along neighboring map zones having major discrepancies with fire behavior characteristics for surface fuel models of similar EVT and that had resulted from the calibration process. The concern was that new seam lines within the data would exist, in terms of fire behavior outputs, if substantial differences in surface fuel models occurred within the same vegetation type and with nothing more than a map zone boundary between them. Smoothing of the surface fuel model layer was completed within the bounding map zones, based on the fuel models selected, average fire season day criteria, and the fire behavior characteristic of rate of spread for the fuel models in question.

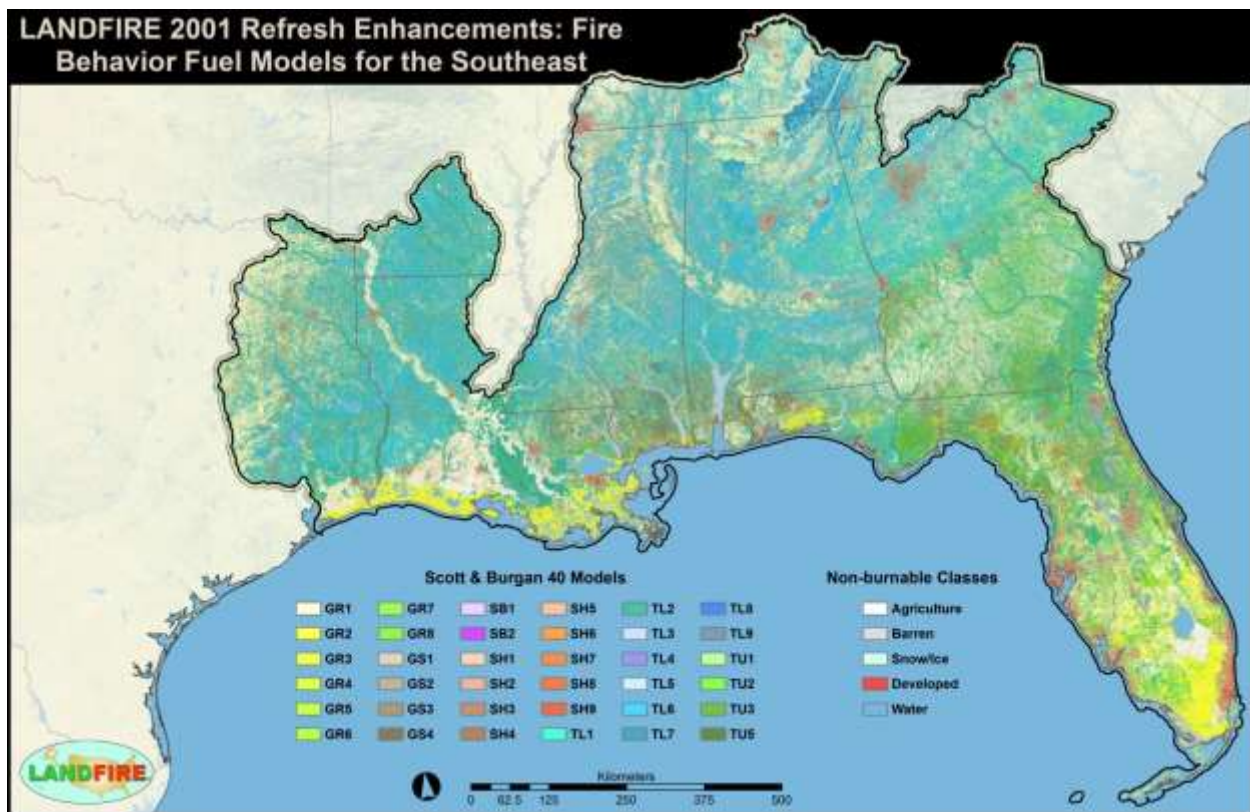

Figure 12 – LF 2001 Fire Behavior Fuel Model 40 for the SE GeoArea

2.6.2b Enhancements to Canopy Fuel

The LF canopy layers CC, CH, CBH, and CBD relate to and were sensitive to changes in EVC and EVH. The CC and CH layers were directly affected by the changes in EVC and EVH, and the grids for CBH and CBD were calculated from the new values in CC and CH. The CBH data layer was developed through exploratory analysis of the LF plot data and statistically analyzed to search for relationships between the

plot level variables and CBH. Unfortunately, no such relationship could be gleaned between these variables. It was determined that CBH would be represented through an averaging method based on combinations of EVT and coarser groupings of EVT with EVH and EVC categories.

The CBD data layer was also developed through exploratory analysis of the LF plot data. The LF plot data were statistically analyzed to search for relationships between the plot level variables and CBD. A General Linear Model (GLM) was developed that expresses the relationship between CBD and CC, CH, and EVT (Reeves et al. 2009).

2.6.2c Modeled Fire Behavior Using LF 2001 Enhanced Products

The Wildland Fire Assessment Tool (WFAT), an ArcMap™ (part of the Esri ArcGIS Desktop suite) tool that uses FlamMap (Finney 2006) to spatially model fire behavior, was used to estimate potential fire behavior using fuel data from LF National and LF 2001. FlamMap is a fire behavior mapping and analysis program that computes potential fire behavior characteristics (spread rate, flame length, fireline intensity, etc.) over an entire landscape for constant weather and fuel moisture conditions. Three fire behavior outputs from these simulations were then compared to quantify changes in LF fuel mapping improvements (Table 30). The changes in estimates of CC and CH had a large effect on the performance of fire behavior models. The WFAT runs used a simulation landscape and a representative Remote Automated Weather Station (RAWS) for each analysis. Fire weather data were generated from the RAWS data for the selected station. The 98th percentile fire weather was used as an input to WFAT to ensure that the conditions were adequate and that WFAT would simulate the burning of the vast majority of pixels in FRG 1-4 (see Table 7 above for FRG definitions).

Table 30 – Comparison of fire behavior characteristics derived from LF National and LF 2001 for Federal Lands in the SE GeoArea.

Table 30. Fire Behavior Comparison – LF National and LF 2001			
Fire Behavior Characteristic	LF National (acres)	LF 2001 (acres)	Percent Change
Flame Length (feet)			
No Fire	5,060,878.7	5,762,009.8	13.9
Low(>0 and <=4)	4,181,445.9	4,274,734.6	2.2
Moderate (>4 and <=11)	1,071,491.8	454,626.8	-57.6
High (> 11)	328,511.9	150,957.1	-54.0
Spread Rate (chains/hour)			
No Fire	5,060,878.7	5,762,036.3	13.9
Low (>0 and <=5)	4,485,465.0	3,973,468.3	-11.4
Moderate (>5 and <=50)	803,299.9	818,589.7	1.9
High (>50)	292,684.7	88,233.9	-69.9
Crown Fire			
No Fire	5,060,878.7	5,762,000.9	13.9
Surface Fire	5,437,463.2	4,705,023.5	(13.5)
Passive Crown Fire	143,984.8	172,370.1	19.7
Active Crown Fire	1.6	2,933.6	188,342.9

2.6.3 LF 2008 Updates to Fire Behavior Products

The LF 2008 process was a modeled attempt to update the vegetation and fuel characteristics depicted in the circa 2001 imagery (LF National) to the more current period of 2008. The main purpose of this process was to incorporate vegetation growth and disturbance over the time period. Regarding fuel characteristics, the changes in surface fuel models (FBFM40, FBFM13) in the disturbed areas were incorporated according to expert opinion, whereas the changes in canopy characteristics were modeled through FVS/FFE.

2.6.3a Updates to Surface Fuel

The FBFM40 and FBFM13, canopy fuels were transitioned from their original assignment in LF 2001 based on type, intensity, and the time since disturbance (Figure 13). Vegetation outside of disturbed areas maintained the same surface fuel model unless there was some change in the EVT. Vegetation was transitioned using the process explained in Section 2.4.3.

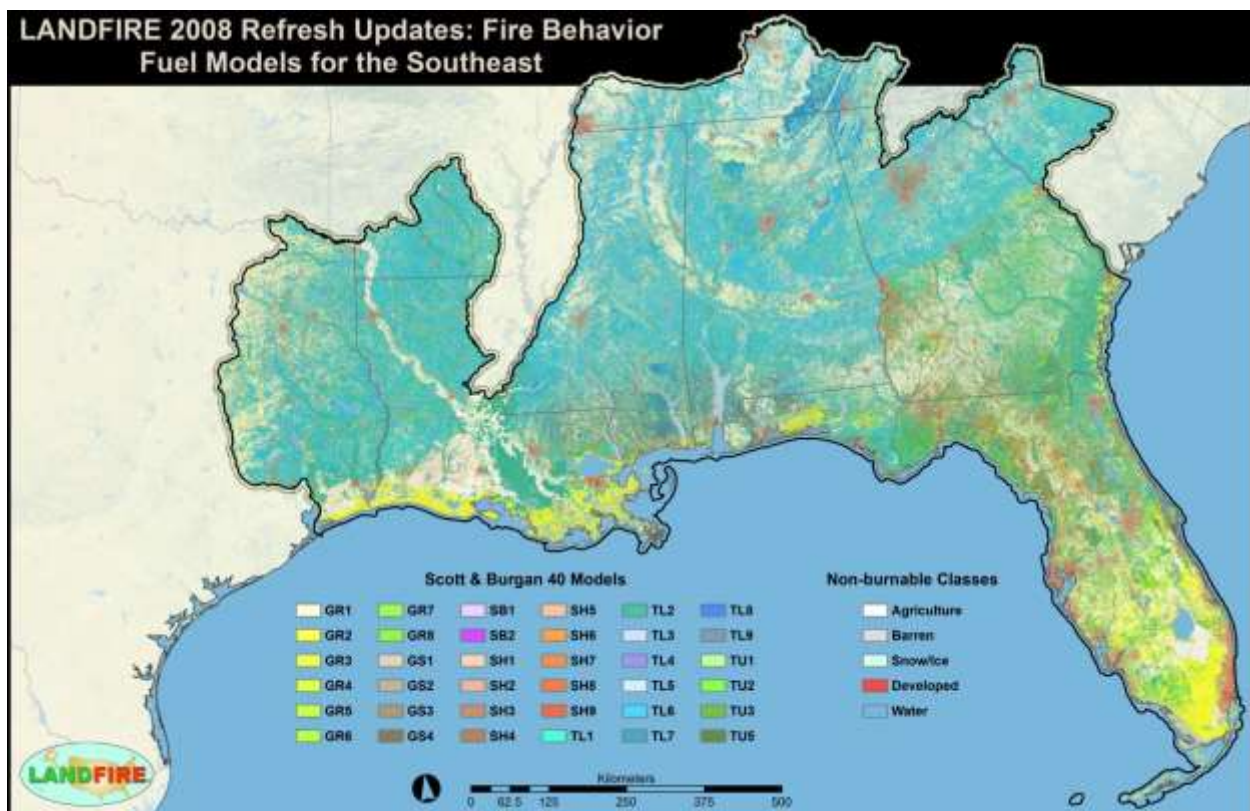

Figure 13 – LF 2008 Fire Behavior Fuel Model 40 for the SE GeoArea.

Time since disturbance was separated into two categories, or time steps. The time steps were 0-3 years post disturbance and 4-10 years. For each time step, one FBFM40 and one FBFM13 were assigned to represent the surface fuel characteristic for the period. Generally, the first step was visualized as a full growing season and the second step was seven years post disturbance. The transitions of surface fuel models in disturbed areas were assigned by the LF fuel team and then sent to regional experts for review and editing.

2.6.3b Updates to Canopy Fuel

The changes in canopy attributes and the growth in non-disturbed areas were modeled through FVS/FFE. Values for CC, CH, and CBD were recalculated using the 2008 EVC, EVH and EVT. The coefficients of change in the CBH attributes were applied to the usual calculation of CBH based on the type, severity, and time since disturbance. Time since disturbance was implemented in two time steps for canopy fuel to reduce the number of fuel model changes to account for 1) 0-3 years post disturbance and 2) 4-10 years post disturbance. For each time step, a CBD value was calculated using the GLM and the updated LF 2008 EVT, EVC and EVH data layers.

The FVS/FFE outputs from these simulations provided disturbance and succession transitions for LF CBH and forested EVTs. The CBH data layers were updated leveraging a coefficient of change that is calculated using a non-disturbed CBH value (derived from FVS) and a disturbance/severity/time step specific CBH value. This coefficient of change was applied against the LF National data in the LF Total Fuel Change Tool (www.nifft.gov). The vegetation transitions were mapped by intersecting the integrated 10-year disturbance map with the LF 2001 vegetation layers. A transition predicted by FVS/FFE was assigned to every disturbance and EVT, height, and cover class on the map. This transition provides the needed data to map LF 2008 EVT in areas where forested EVTs were disturbed or may have succeeded to different conditions.

2.6.3c Modeled Fire Behavior Using LF 2008 Updated Products

The WFAT was used to estimate potential fire behavior using fuel data from LF 2001 and LF 2008. Three fire behavior outputs from these simulations were then compared to quantify changes in LF fuel mapping improvements (Table 31). The WFAT runs used a simulation landscape and a representative RAWS for each analysis. Fire weather data were generated from the RAWS data for the selected station. The 98th percentile fire weather was used as an input to WFAT to ensure that the conditions were adequate and that WFAT would simulate the burning of the vast majority of pixels in FRG I-IV.

Table 31 – Comparison of fire behavior characteristics derived from LF 2001 and LF 2008 for Federal Lands in the SE GeoArea.

Table 31. Fire Behavior Comparison – LF 2001 and LF 2008			
Fire Behavior Characteristic	LF 2001 (acres)	LF 2008 (acres)	Percent Change
Flame Length (feet)			
No Fire	5,762,009.8	5,933,965.6	3.0
Low(>0 and <=4)	4,274,734.6	4,088,045.5	-4.4
Moderate (>4 and <=11)	454,626.8	400,682.0	-11.9
High (> 11)	150,957.1	219,635.1	45.5
Spread Rate (chains/hour)			
No Fire	5,762,036.3	5,934,000.8	3.0
Low (>0 and <=5)	3,973,468.3	3,705,068.7	-6.8
Moderate (>5 and <=50)	818,589.7	923,779.9	12.9
High (>50)	88,233.9	79,478.9	-9.9
Crown Fire			
No Fire	5,762,000.9	5,933,956.1	3.0
Surface Fire	4,705,023.5	4,456,137.1	-5.3
Passive Crown Fire	172,370.1	247,147.8	43.4
Active Crown Fire	2,933.6	5,087.3	73.4

2.7 Fire Effects

2.7.1 Product Description

The LF fire effects data layers describe the composition and characteristics of both surface fuel loadings and canopy fuel loadings, including Fuel Characteristic Classification System Fuelbeds (FCCS) (Ottmar et al. 2007) and FLM (Lutes et al. 2009). These geospatial products may be used within models to predict the effects of wildland fire. These data are useful for strategic fuel treatment prioritization and tactical assessment of fire behavior and effects.

FCCS defines a fuelbed as the inherent physical characteristics of fuel that contribute to fire behavior and effects (Riccardi et al. 2007). It is a set of measured or averaged physical fuel characteristics of a relatively uniform unit on the landscape that represents a distinct fire environment. An FCCS fuelbed can represent any scale or precision of interest. In FCCS, fuelbeds represent realistic fuel conditions and can accommodate a wide range of fuel characteristics in six horizontal fuel layers called strata (Ottmar et al. 2007). The strata include canopy, shrub, non-woody vegetation, woody fuel, litter/lichen/moss, and ground fuel. Each stratum is further divided into 16 categories and 20 subcategories to represent the complexity of wildland and managed fuel. FCCS fuelbeds were developed by the Fire and Environmental Applications Team (FERA) at the USFS Pacific Wildland Fire Sciences Laboratory to represent important fuel types in the United States. FCCS fuelbeds contain data from the following sources: regional workshops; published literature; USFS photo series, general technical reports, and research papers; other government literature and large databases (such as the NPS and FIA); masters and doctoral theses; white papers, field data, and other unpublished data; and expert opinion.

The LF FLM classification system used for CONUS was based on unique sets of fuel characteristics that simplified the input of fuel loadings into fire effects models. FLMs can be used to simulate smoke emissions and soil heating. An FLM fuelbed is defined as all combustible material below 2 meters and above mineral soil. These fuels are commonly referred to as surface fuels and include live and dead herbaceous and shrub material, DWM, duff, and litter. Fire behavior and fire effects are the result of the combustion process of the fuel. The size and spatial distribution of smaller diameter combustible material, for example, affects fire behavior, whereas fire effects are dependent on the intensity and duration of the combustion of all fuel. This generalization suggests that a fuel classification system that emphasizes substantial differences in fire behavior will not be the same as a classification that identifies differences in fire effects. The FLMs developed for LF were designed to uniquely identify substantial differences in two fire effects: maximum surface soil heating and total fine particulate matter emissions less than 2.5 micrometers in diameter (PM_{2.5}).

2.7.2 LF 2001 Enhancements to Fire Effects Products

2.7.2a Enhancements to the Fuel Characterization Classification System fuelbeds

The FCCS fuelbed mapping relied almost entirely on the LF EVT layer. In cases where an FCCS fuelbed represented a certain seral stage or density class of a particular EVT, the LF EVC layer and EVH layer were also used for mapping FCCS fuelbeds. In addition, the NLCD mapping zone layer, which was used for LF mapping, was used to reflect broader eco-regional variation in FCCS fuelbeds. The mapping process was a collaborative effort between LF and FERA.

The following were the steps involved in the FCCS mapping process. First, the construction of an initial cross-walk of FCCS fuelbeds to LF EVTs using the Society of American Foresters and Society of Range Management classification scheme was used as a link for each completed LF mapping zone. Second, FCCS fuelbeds were identified that did not match well with LF EVT map units. These new fuelbeds were then created and assigned all FCCS attributes. A final cross-walk was constructed that included all new fuelbeds identified in the previous step. The final step used a map rule set tied to the cross-walk to produce the final FCCS fuelbed layer for each mapping zone.

With the inclusion of a new method to determine EVC and EVH, the rule sets that were created for FCCS remained the same, but the pixels on the map that each rule applied to shifted, depending on the change in tree cover and/or height of the tree cover in forested EVTs. Table 32 and Table 33 display the FCCS rule sets developed for EVT 2027 and 2028 in mapping zone 7. LF National and LF 2001 depict the change in acreage between data versions. For example, Table 32 depicts the rule sets and the appropriate FCCS fuelbeds. The number of acres and the percent of each EVT that meet those criteria are also shown. These are examples of the rule sets for two EVTs in mapping zone 7, Table 33. The amount of area affected by each rule set changed substantially. However, even though the area affected by each rule set changed, the rule sets remained the same between LF National and LF 2001.

Table 32 – LF National Mapping Zone 07 Fuel Characteristic Classification System fuel rule sets and number of acres based on the range of Existing Vegetation Cover and Existing Vegetation Height values.

Table 32. LF National Fuel Rule Sets					
EVT	Percent Cover	Range of Height (m)	FCCS	Acres	Percent EVT
2027 Med Dry-Mesic Mixed Conifer	10 - 19	0 - 25	4	43,706	3.9
2027 Med Dry-Mesic Mixed Conifer	10 - 19	25 - 50	16	4,769	0.4

2028 Med Mesic Mixed Conifer	20 - 100	10 - 50	7	2,552,843	97.7

2.7.2b Enhancements to the Fuel Loading Models

Following the methods outlined by Lutes et al. (2009) and Sikkink et al. (2009), fire effects modeling was conducted using the First Order Fire Effects Model (FOFEM) version 5.9 to simulate PM_{2.5} smoke emissions and soil heating. Pseudo-plots (a method to address a lack of field data using existing plot and geospatial data) with loading attributes were developed for grasslands using the loading data from FCCS. For some FLMs, the shrub loading in the LF National attributes from Sikkink et al. (2009) summed shrub and herb loading into shrub loading. Fire effects were run on these data for a comparison with a professional judgment split of the loading between shrub and grass. The burnable agriculture and burnable urban types with loading attributes were also included in these data. A series of iterative cluster analyses of fire effects, fuel loading, and data subsets were then performed to (1) validate the addition of grassland models, (2) separate shrub loading into shrub and herb loading, (3) cross-walk the NLCD types to an FLM, and (4) evaluate whether the classification was adequate to deal with post-disturbance conditions. The results indicated that the addition of three grassland models with low, moderate, and high grass fuel loading, in combination with the separation of shrub and grass loading greatly enhanced the separation of the fire effects clusters and achieved objectives. The burnable

LANDFIRE 2001 and 2008 Methods and Results

agriculture and burnable urban types with fuel loading were cross-walked to an FLM model. These analyses resulted in 30 FLMs, with some adjustment in the loading attributes.

FLM mapping methods applied rules developed from the LFRDB plot data for assignment of a given FLM to various combinations of EVT, EVC, and EVH. For the western U.S., fuel bed measurements of coarse woody debris (CWD), fine woody debris, duff, and litter were compiled from the LFRDB for 24 LF zones. These data and subsequent rules were then used for mapping FLM in the SE GeoArea. Of 17,708 fire effects records, 2,813 had the necessary measurements to match to a FLM. The following procedures outline how plot level data were used to create seamless maps for all LF zones.

A fuelbed measurement majority method was applied to map FLMs, which are depicted by Figure 14. This mapping process included the following steps:

1. Fire effects data were compiled from the LFRDB from all available LF zones.
2. These data were classified to their appropriate FLM.
3. The majority FLM was identified based on existing vegetation database attribute combinations.
4. FLM layers were produced and processed using a pixel populating routine.

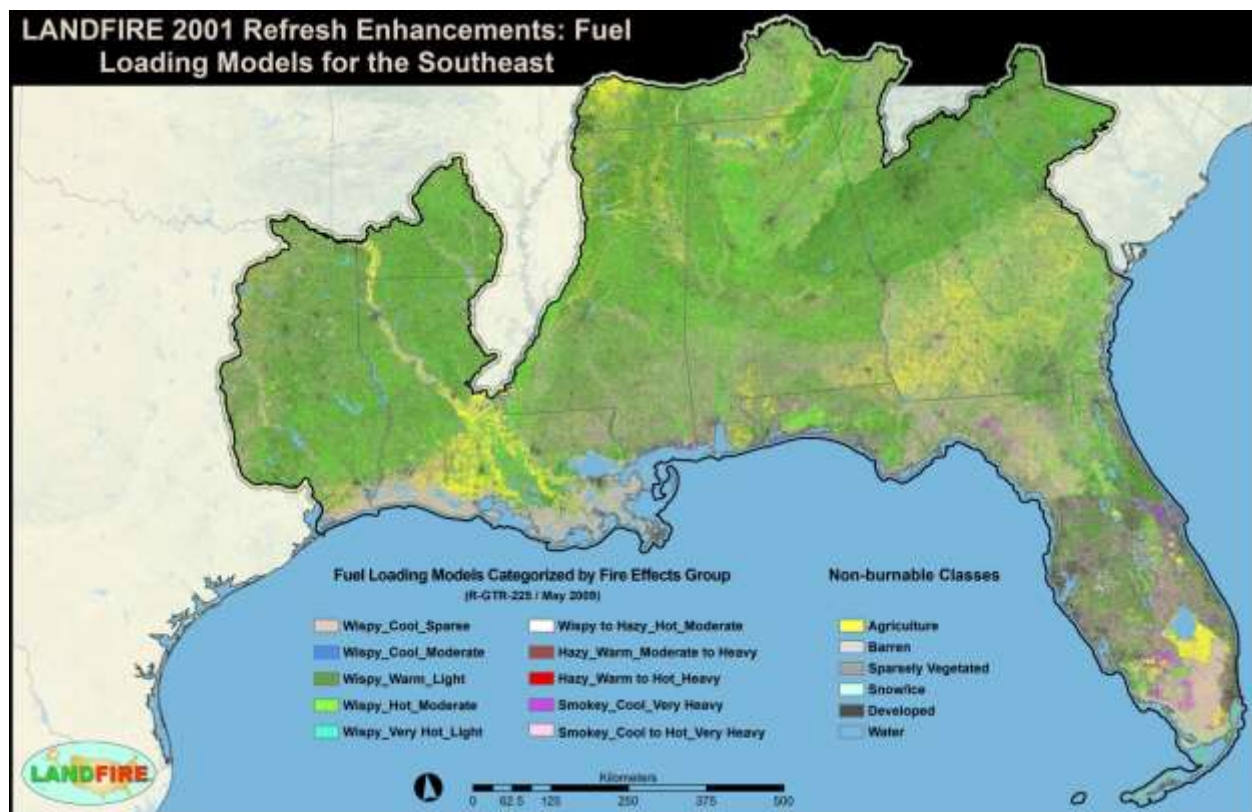

Figure 14 – LF 2001 Fuel Loading Models for the SE GeoArea. FLM categories are from Sikkink et al. (2009).

2.7.2c Modeled Fire Effects Using LF 2001 Enhanced Products

The WFAT can also be used to spatially model fire effects using FOFEM, and was used to estimate potential fire effects using fuel loading data from LF National and LF 2001. Three fire effects outputs from these simulations were then compared to quantify changes in LF FLM mapping improvements

(Table 34). The WFAT used a simulation landscape and a representative RAWS for each area. Fire weather data were generated from the RAWS data for the selected station. The 98th percentile fire weather was used as an input to WFAT. The FLM grids provided the loadings data for these simulations.

Table 34 –Comparison of fire effect characteristics derived from LF National and LF 2001 for Federal Lands in the SE GeoArea.

Table 34. Fire Effect Characteristics Comparison – LF National to 2001			
Fire Effect Characteristics	LF National (acres)	LF 2001 (acres)	Percent Change
Particulate Production:			
No Effect	7,092,648.9	7,451,579.7	5.1
Low (>0 and <=250 lbs/ac)	3,193,784.3	3,084,683.6	-3.4
Moderate (>250 and <=1000 lbs/ac)	111,923.8	23,053.7	-79.4
High(>1000 lbs/ac)	243,971.1	83,012.3	-66.0
Soil Heating:			
No Effect	10,612,835.5	10,613,131.0	0.0
Low (>0 and <=3 cm)	-	-	0.0
Moderate (>3 and <=8 cm)	-	-	0.0
High(>8 cm)	29,492.7	29,198.2	-1.0

2.7.3 LF 2008 Updates to Fire Effects Products

2.7.3a Updates to Fuel Characterization Classification System Fuelbeds

The same mapping rules that were used for LF 2001 were used for LF 2008 in areas not disturbed by either fire, mechanical removal of surface fuel, or mechanical or wind addition of surface fuel. However, pixels that were affected by disturbances between 1999 and 2008 were adjusted using a simple rule set that modified the original FCCS assignment based on disturbance type, severity, and time since disturbance described in Section 2.4.3.

2.7.3b Updates to Fuel Loading Models

The same mapping rules (see Section 2.7.2) that were used for LF 2001 were used for LF 2008 in areas not disturbed by either fire, mechanical removal of surface fuel, or mechanical or wind addition of surface fuel. However, pixels that were affected by disturbances prior to 2008 were adjusted using a simple rule set that modified the original FLM assignment based on disturbance type, severity, and time since disturbance. LF 2008 FLMs are represented in Figure 15.

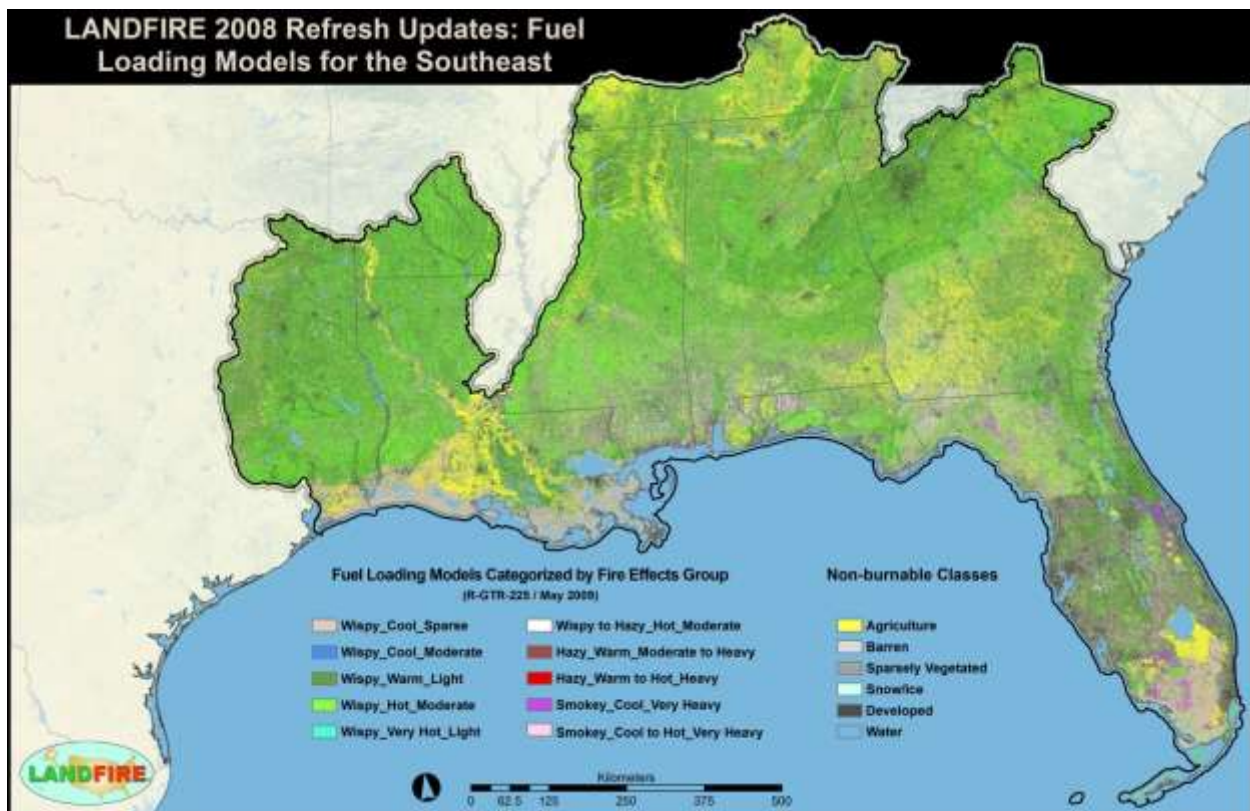

Figure 15 – LF 2008 Fuel Loading Models for the SE GeoArea. Categories are from Sikkink et al. (2009).

2.7.3c Modeled Fire Effects Using LF 2008 Updated Products

WFAT was used to estimate potential fire effects using fuel loading data from LF 2001 and LF 2008. Three fire effects outputs from these simulations were then compared to quantify changes in LF fuel loading mapping improvements (Table 35). The WFAT runs used a simulation landscape and a representative RAWS for each area. Fire weather data were generated from the RAWS data for the

selected station. The 98th percentile fire weather was used as an input to WFAT. The FLM grids provided the loadings data for these simulations. The large change in the moderate class is likely due to the combined effects of succession, which would move pixels from low to moderate, and landscape disturbance - mainly mechanical - which would move pixels from high to moderate.

Table 35 – Comparison of fire effect characteristics derived from LF 2001 and LF 2008 for Federal Lands in the SE GeoArea.

Table 35. Fire Effect Characteristics Comparison– LF 2001 to LF 2008			
Fire Effect Characteristics	LF 2001 (acres)	LF 2008 (acres)	Percent Change
Particulate Production:			
No Effect	7,451,578.7	7,677,756.0	3.0
Low (>0 and <=250 lb./ac)	3,084,683.6	2,647,382.7	-14.2
Moderate (>250 and <=1000 lb./ac)	23,053.7	303,545.5	1,216.7
High(>1000 lb./ac)	83,012.3	13,643.9	-83.6
Soil Heating:			
No Effect	10,613,130.0	10,579,478.3	-0.3
Low (>0 and <=3 cm)	-	-	0.0
Moderate (>3 and <=8 cm)	-	-	0.0
High(>8 cm)	29,198.2	62,849.9	115.3

2.8 Fire Regime Products

2.8.1 Product Description

Broad-scale alterations of historical fire regimes and vegetation conditions have occurred in many landscapes in the U.S. through the combined influence of land management practices, fire exclusion, ungulate herbivory, insect and disease outbreaks, climate change, and invasion of non-native plant species. The LF Program produced maps of historical fire regimes and historical vegetation conditions using a state and transition model, VDDT. The LF Program also produced maps of current vegetation and measurements of current vegetation departure from simulated historical reference conditions. The LF 2001/2008 update was accomplished by using the FRCC Mapping Tool (FRCCMT; Jones and Tirmenstein, 2012) to perform the FRCC calculations as defined in the Interagency Fire Regime Condition Class Guidebook (Fire Regime Condition Class, 2010). FRCCMT relied on the use of a variety of spatial inputs, including the BpS and SCLASS layers and LF 2001 Fire Regime Landscape layers.

SCLASS categorizes current vegetation composition and structure in up to five successional states defined for each LF BpS model. Two additional categories define uncharacteristic vegetation components that were not found within the compositional or structural variability of successional states defined for each BpS model, such as exotic species. These succession classes were similar in concept to those defined in the FRCC Guidebook. The FRCC data layer categorizes departure between current vegetation conditions and reference vegetation conditions according to the methods outlined in the FRCC Guidebook. This departure index is represented using a 0 to 100 percent scale, with 100 representing maximum departure. The departure index was then classified into three condition classes.

It is important to note that the LF FRCC approach differs from that outlined in the FRCC Guidebook as follows: LF FRCC was based on departure of current vegetation conditions from reference vegetation conditions only, whereas the Guidebook approach also includes departure of current fire regimes from those of the reference period. As such, LF has made a transition from calling these products FRCC data products to Vegetation Condition Class (VCC). Similarly, the FRCC departure has been changed to Vegetation Departure Index (VDEP).

2.8.2 LF 2001 Enhancements to Fire Regime Products

2.8.2a Enhancements to Summary Units

The LF 2001 fire regime product was developed to provide a spatial summary unit for processing within each GeoArea using the FRCCMT. The layer was developed by combining the Hydrologic Unit Code (HUC) and the FRCC layer and clipping this combined raster to each GeoArea boundary. The FRCC layer was then summarized by HUC codes 8, 10, and 12. The fire regime product is one of five inputs used in analyzing departure with FRCCMT, allowing for scale-appropriate analyses for each stratum according to its associated FRG (FRCC, 2010). The outputs from FRCCMT differ as the landscape used to report those results changes in size and/or shape. It is therefore important to select appropriately sized landscapes when using FRCCMT. In addition to the fire regime product, FRCCMT assesses the FRCC metrics by BpS within the landscape watersheds, using the smaller sub-watersheds denoted by the HUC 12 code to calculate FRCC for BpS in FRG 1 and 2, the watersheds denoted by the HUC 10 code to calculate FRCC for BpS in FRG 3, and the larger sub-basins denoted by the HUC 8 code to calculate FRCC for BpS in FRG 4 and 5.

2.8.2b Enhancements to Succession Classes

The SCLASS layer was created by linking the BpS Group attribute in the BpS layer with the RMT data and assigning the SCLASS attribute. This geospatial product displays a reasonable approximation of SCLASS, documented in the RMT. The current successional classes and their historical reference conditions were compared to assess departure of vegetation characteristics; this departure can be quantified using methods such as FRCC. SCLASS rules for each BpS were designed to meet the following criteria: 1) represent the existing locations of a BpS SCLASS on the landscape and 2) meet the input requirements for the FRCCMT. User feedback had identified two primary issues with the LF National BpS SCLASS rules.

1. Many of the rules in the RMT database conflicted due to overlapping cover and height ranges.
2. Some life forms that were mapped within a given BpS should not have been included based on the BpS model description for the SCLASS. These cases are referred to as “life-form mismatches.”

BpS models and SCLASS rules were evaluated against the BpS model descriptions and adjusted to accurately reflect the intent of the model. In some cases the cover and height values either matched or remained similar to the original model. In other cases the cover and height values were adjusted considerably. The SCLASS rule revision process eliminated overlap between cover and height ranges of the SCLASS rules for a given BpS. Overlapping rules were edited so that only one rule applied to each pixel. In some cases correcting the overlapping values resulted in cover or height values that were one or more categories above or below the original model.

LANDFIRE 2001 and 2008 Methods and Results

In the case of life-form mismatches, the life forms that were mapped as part of the BpS but not allowed by the SCLASS rules were reviewed and reassigned to an uncharacteristic class and the probable source of the error was documented.

The state and transition model for SCLASS is defined as follows: 1) S-Class A: early-seral, post replacement; 2) S-Class B: mid-seral, closed canopy; 3) S-Class C: mid-seral, open canopy; 4) S-Class D: late-seral, open canopy; and 5) S-Class E: late-seral, closed canopy. The SClass for the SE GeoArea is represented in Figure 16. Not all biophysical settings conform to this model. For example, some grassland types might have only two or three succession classes (Fire Regime Condition Class, 2010).

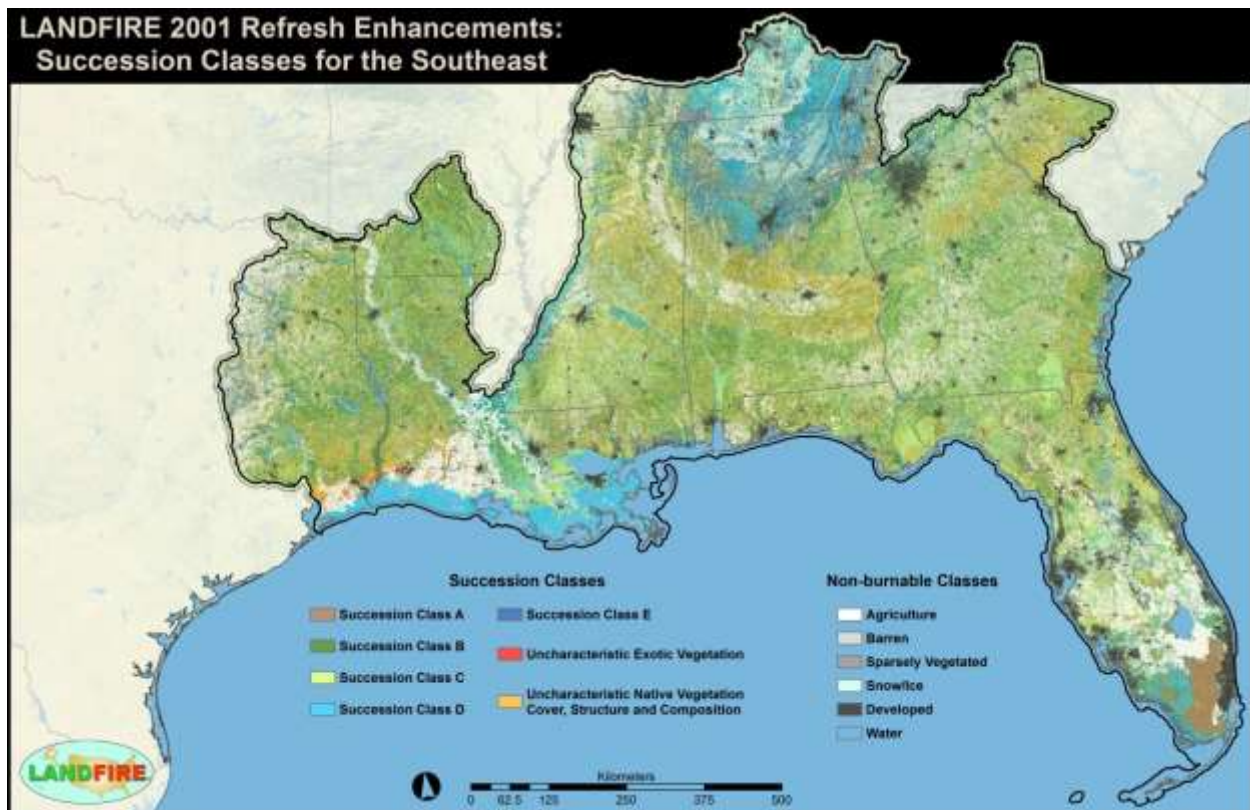

Figure 16 – Map of LF 2001 enhancements of the Succession Classes layer for the SE GeoArea.

2.8.2c Enhancements to Vegetation Departure

Unlike previous versions of LF data, reference conditions of percent composition for each of the characteristic SCLASS were derived from modeling workshops with the intent to approximate the definitions outlined in the FRCC Guidebook. Modelers used the VDDT, which uses state and transition landscape modeling to simulate the effect that disturbance and management actions have on a landscape over time. The results of this modeling are stored in the LF RMT.

The current conditions were derived from the corresponding version of the LF SCLASS data layer. The areas currently mapped to agriculture, urban, water, barren, or sparsely vegetated BpS units were not included in the FRCC calculation; thus, FRCC is based entirely on the remaining area of each BpS unit that is occupied by valid SCLASS. To calculate the Stratum Vegetation Departure, FRCCMT used the BpS

layer along with a HUC within the layer to stratify the SCLASS layer. Once the SCLASS layer was stratified by a HUC and BpS, FRCCMT was able to calculate the Current Percent Composition for each SCLASS within each BpS at the appropriate HUC level.

FRCCMT then used the Current Percent Composition for each of the SCLASS within a BpS/HUC along with the corresponding Reference Percent Compositions for that BpS from the Reference Condition Table to calculate the Stratum Vegetation Departure, which is described above. The Stratum Vegetation Departure grid was calculated by comparing the Reference Percent Composition of each SCLASS to the Current Percent Composition, summing the smaller of the two for each of the SCLASS to determine the Stratum Similarity. This value was then subtracted from 100 to determine the Stratum Vegetation Departure. The VCC grid (Figure 17) is a 3-category classification of the Stratum Vegetation Departure based on the following thresholds:

1. VCC I: Stratum Vegetation Departure of 0 to 33
2. VCC II: Stratum Vegetation Departure of 34 to 66
3. VCC III: Stratum Vegetation Departure of 67 to 100

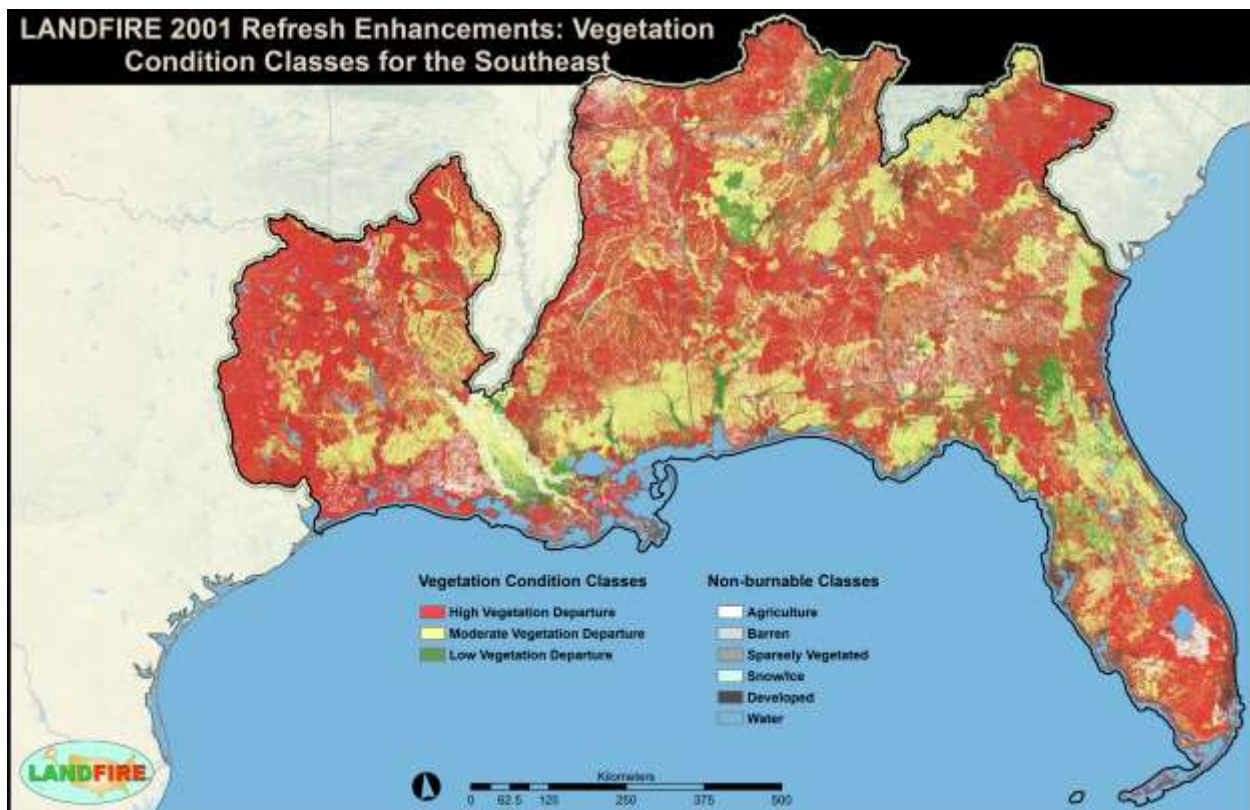

Figure 17 – Map of Vegetation Condition Class for the SE GeoArea from LF 2001 enhancements.

2.8.3 LF 2008 Updates to Fire Regime Products

2.8.3a Updates to Succession Classes

The same SCLASS mapping rules (see Section 2.8.2) that were used for LF 2001 were used for LF 2008. Mapping rules were applied to LF 2008 EVT, EVC, and EVH layers to map the LF 2008 SCLASS layer (Figure 18).

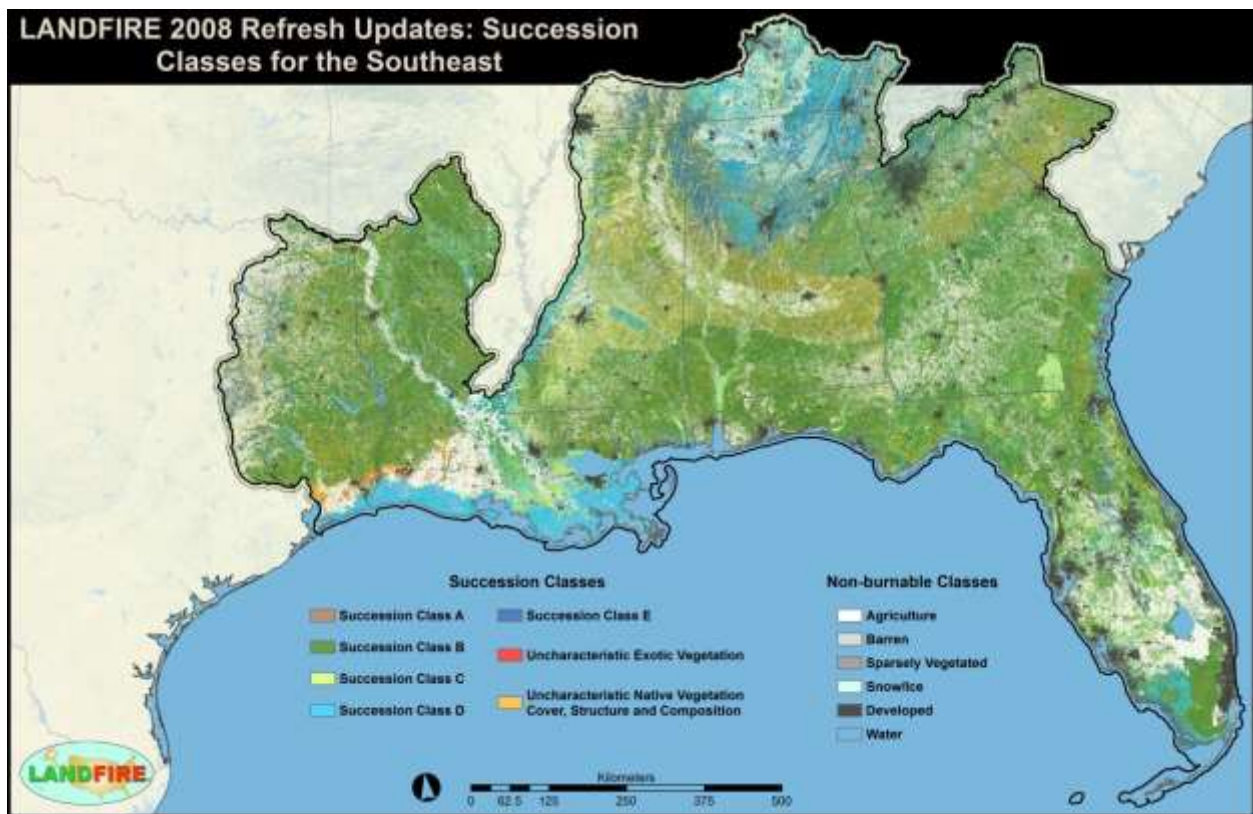

Figure 18 – Map of LF 2008 updates of the Succession Classes layer for the SE GeoArea.

2.8.3b Updates to Vegetation Departure

FRCCMT was used to calculate the current percent composition for each of the LF 2008 SCLASS within a BpS/HUC along with the corresponding reference percent compositions for that BpS from a reference condition table to calculate the LF 2008 stratum vegetation departure. The LF 2008 VCC grid was derived from a 3-category classification of the stratum vegetation departure as defined in Section 2.8.2c (Figure 19).

1. VCC I: Stratum Vegetation Departure of 0 to 33
2. VCC II: Stratum Vegetation Departure of 34 to 66
3. VCC III: Stratum Vegetation Departure of 67 to 100

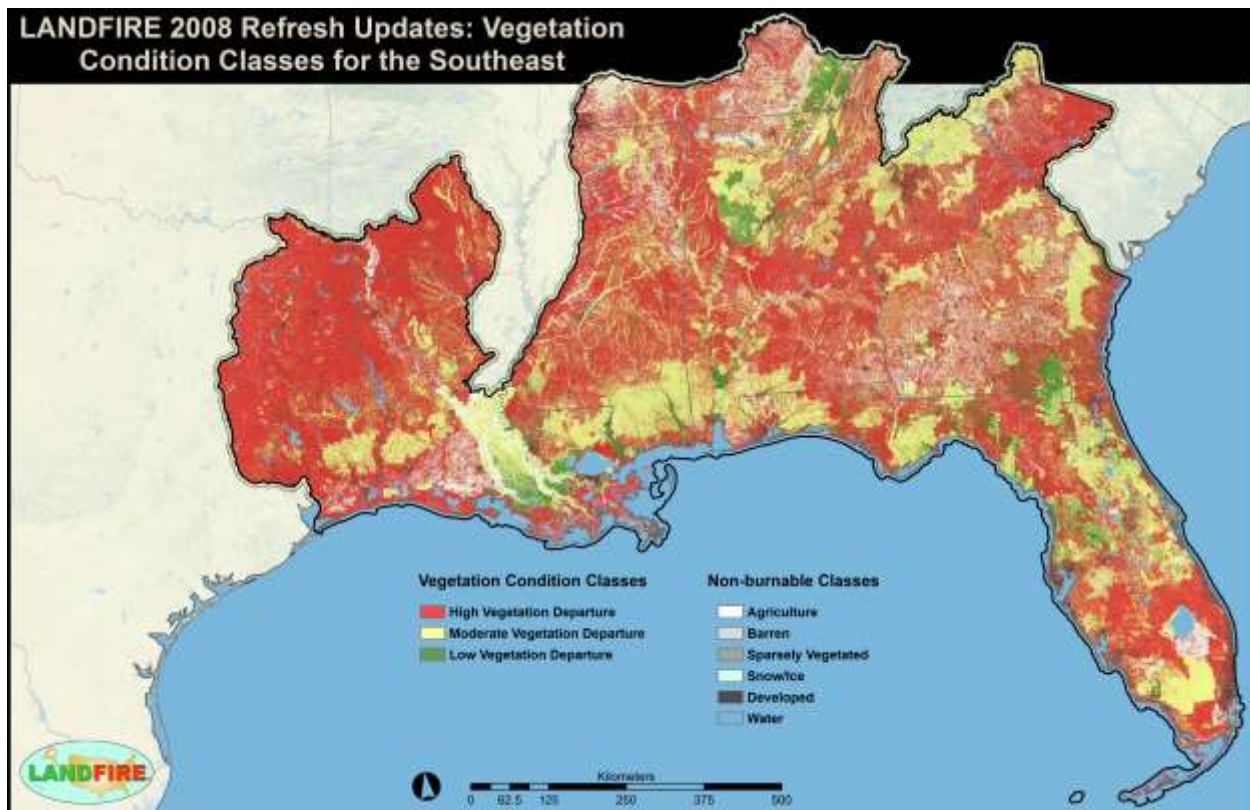

Figure 19 – Map of Vegetation Condition Class for the SE GeoArea from LF 2008 updates.

3.0 FARSITE Comparison of LANDFIRE Fuel Characteristics Versions

This section evaluates one or more of the LF fuel data sets against known wildland fire perimeters, spread distances, and environmental conditions to determine the efficacy of the data for fire analyses using the FARSITE program to perform comparison between LF data sets with the final perimeters of an actual wildland fire. Fires were selected from one of several sources, either the MTBS Fire Occurrence Database for each of the representative geographic areas, National Interagency Fire Center, or from personal contact with fire personnel related to the fire. The LF data sets that were used throughout this process were FBFM13 and FBFM40, CC, CH, CBH, and CBD from LF National, LF 2001, and LF 2008. Slope, elevation, and aspect were also included as inputs. Below are two examples of a comparison between LF data sets with the final perimeters of an actual wildland fire.

3.1 Airport Fire, 2007

The Airport Fire occurred in central Florida (LF map zone 55) in early May of 2007 just north of Daytona Beach. Information about the fire in terms of suppression actions were limited and the first available perimeter was from May 5th. The fire reached its final size of just under 6,000 acres on May 8th. The Energy Release Component (ERC – a National Fire Danger Rating System index related to how hot a fire could burn) was above the 90th percentile the first week in May and was above the 97th percentile on May 8th compared to previous years. For this analysis, an Energy Release Component (ERC-G / Gridded) was used for derived weather forecast data from reporting stations using a 5-km grid. Also, fire activity was accelerated because greater than average wind speeds occurred during May.

The vegetation in the fire site was composed of the following LF EVTs, Central Florida Pine Flatwoods (EVT 2453) which was 90% of the fire area. The other 10% was nearly equally divided between, Managed Tree Plantation- Southeast Conifer and Hardwood Group (EVT 2535), and Gulf and Atlantic Coastal Plain Swamp Systems (EVT 2480).

3.1.1 Inputs

Weather, wind, and fuel moisture data used in the fire simulations were from the Lake George RAWS, which is located in close proximity to the fire site. Wind speeds at the 20-foot (ft) (6 meter) level ranged from 8 to 12 miles per hour (mph) and wind gusts were recorded into the upper 20 mph range with directions from the east and southeast. The hourly mid-point value between the 10-minute average and maximum gust wind speed and wind direction values were used in the simulation. The weather conditions from the Lake George weather station were used to estimate beginning dead fuel moisture, but live herbaceous fuel moisture was adjusted lower than the RAWS values.

LF National and LF 2001 only differed in surface fuel models (FBFM40) within EVT 2453 - Central Florida Pine Flatwoods, where the changes in cover and/or height between the two LANDFIRE versions occurred. The version differences resulted in FBFM40 fluctuations between a Timber Understory (TU) 3 (163), Timber Litter (TL) 6 (186), and TL2 (182) in the landscape file. In LF 2008, the surface fuel models

FARSITE Comparison of LANDFIRE Fuel Characteristics Versions

depicted the site after the 2007 Airport Fire event and the FBM40 layer was composed mainly of TL6 and heavy grass shrub at the fire origin area.

Crown fire activity should be more prolific in projections that use LF 2001 data than from projections using LF National data due to the differences in values for CBH. Canopy Base Height in LF National is generally 6 m and greater, whereas, in LF 2001 they are generally less than 4 m, with some pixels being in the 2 meter (m) range. After a disturbance is added to LANDFIRE, (similar to the 2007 Airport Fire being updated in LF 2008) the CBH increases to generally 5 m due to the fire burning and clearing out lower canopy heights, however, some areas persist in the less than 2 m range due to lower fire behavior activity.

Several different burning analyses were simulated for this analysis. The final extent of the fire was simulated to grow to the roads in the area. These roads served as the control lines that were used for suppression actions on May 8th. Prior to this time period, it appears there could have been a single large fire spread event that accounted for most of the interior acres burned.

For this analysis, an 8-hour maximum burn window was simulated with each version of the LF fuel data as an attempt to replicate the actual event. The LF 2001 landscape was used to perform a 2-day spread simulation in two 8-hour maximum burn periods because the dates of the perimeters suggest there may have been multiple spread events. The burn period length was derived from the hours where low fuel moisture conditions existed and high wind speed values were indicated in the RAWS data. The ignition point was set to the toe (SE corner) of the fire in all three versions of the LF data landscape files. Crown fire activity was set to the Scott and Reinhardt method (Scott and Reinhardt, 2001) and spotting was enabled at 0.9%. A fuel moisture and environmental conditioning period was used from May 5th through May 7th with the simulation conducted through May 8th. In the 2-day simulation, the conditioning period began on May 4th with the simulation conducted through May 7th and 8th.

3.1.2 Results

The Airport Fire perimeter from May 7th is depicted in Figure 20. This was the first perimeter available for the analysis. The assumption for the first set of analyses was that the fire extent was reached in a single burn period and the origin was in the narrow southeast alley of the perimeter.

Figure 20 – Airport Fire Perimeter May7th. The main burn area of the fire extended nearly 10 kilometers from northwest to southeast.

LF National simulations were processed several times to calibrate the model and resulted in half of the area of the fire perimeter was projected to burn as displayed in Figure 21.

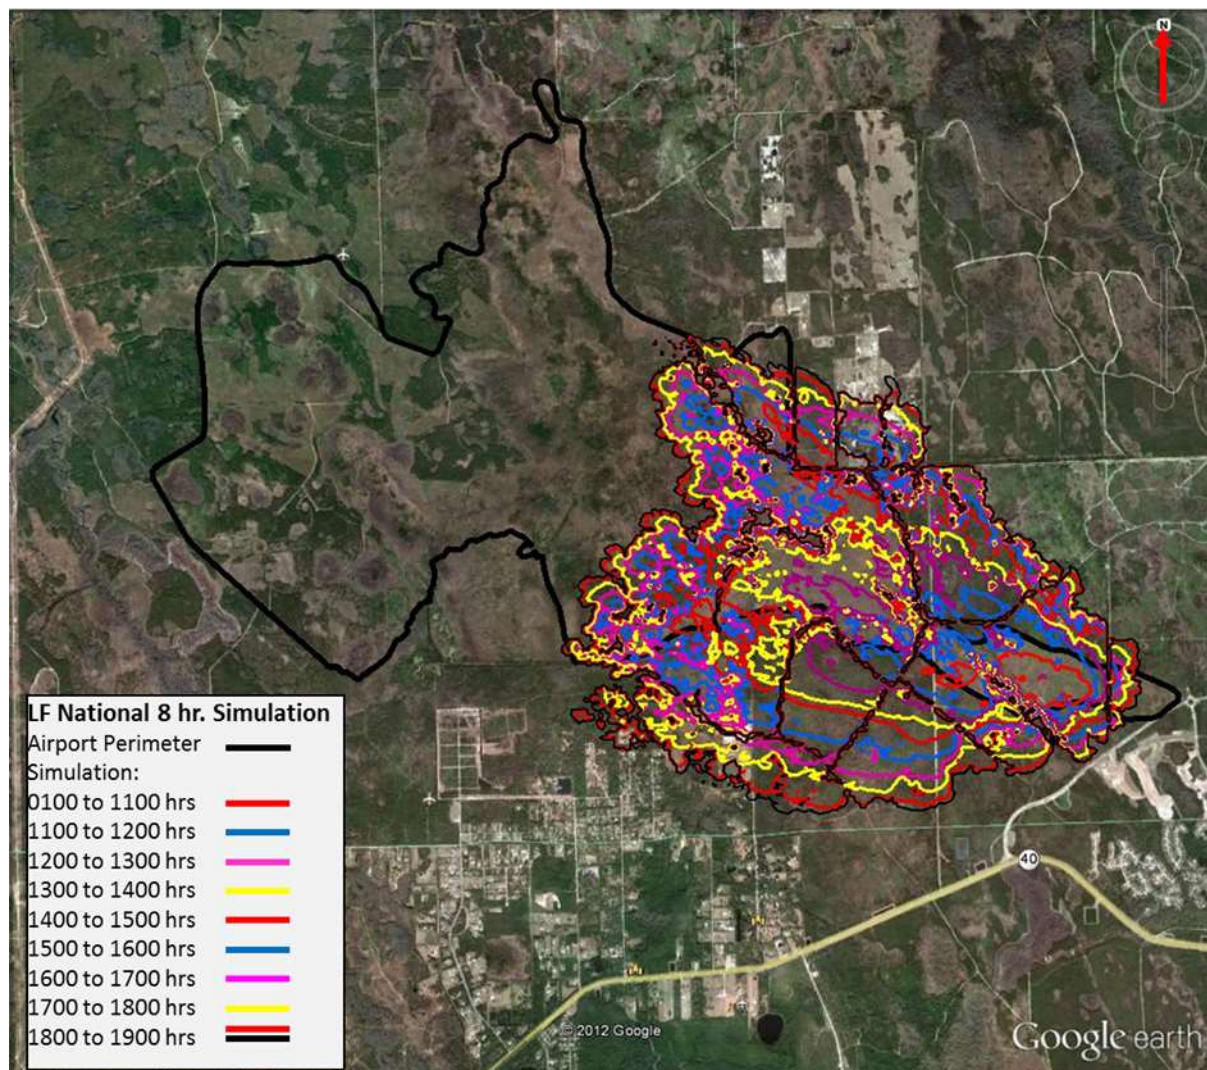

Figure 21– LF National Landscape Simulation for the Airport Road Fire 2007. The main burn area of the fire extended nearly 10 kilometers from northwest to southeast.

The differences in fire perimeter sizes from the results from the simulations were attributed to varying live fuel moisture values and CBH in the LF National data set. For all simulations, wind speed was held constant to the mid-point between the 10-minute average and wind gusts from the Lake George RAWS. The perimeter in Figure 21 was based on an herbaceous fuel moisture of 60% and woody fuel moisture of 85%, which was slightly less than the herbaceous fuel moistures and the woody fuel moisture projected from the RAWS.

LF 2001 simulation (Figure 22) used the same time frames and inputs for fuel moisture, wind, and weather as the LF National simulation. The difference in fire spread and simulated fire perimeter was due to some crown fire activity in the model as a result of the differences in values for CBH mentioned above between LF National and LF 2001. The LF 2001 landscape simulated fire spread further into the interior than the LF National data set.

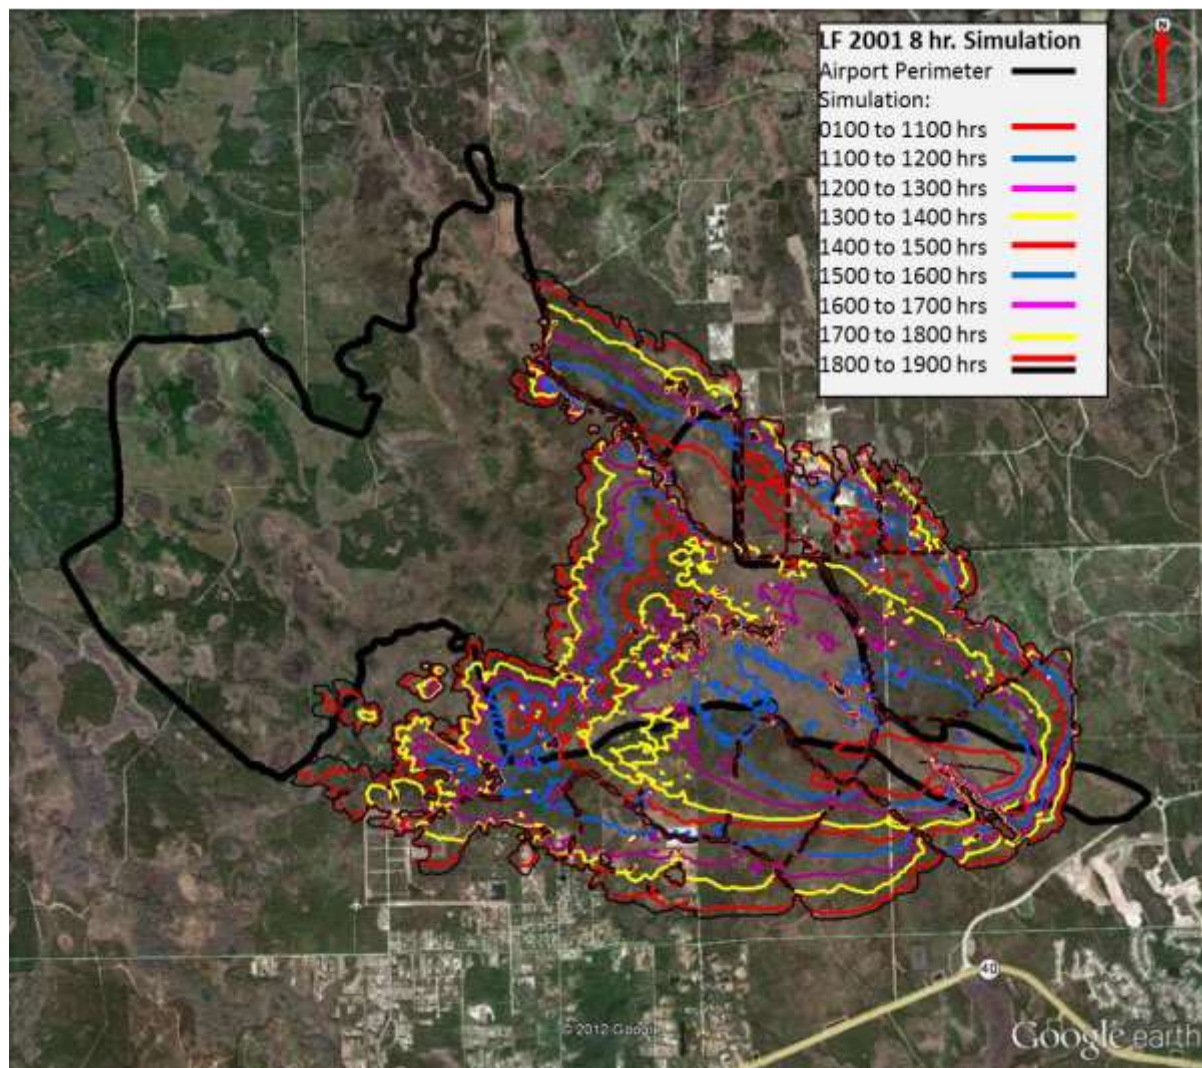

Figure 22- LF 2001 Simulation of Airport Road Fire. The main burn area of the fire extended nearly 10 kilometers from northwest to southeast.

The LF 2008 simulation (Figure 23) depicted the fire area a year after the fire event and as a result some of the LANDFIRE vegetation characteristics reflect disturbance conditions in terms of fuels. However, the simulated fire spread in the landscape (shown in Figure 23) is similar to the fire spread in LF National, which is representative of the quick regrowth of burnable vegetation in these Southeastern landscapes.

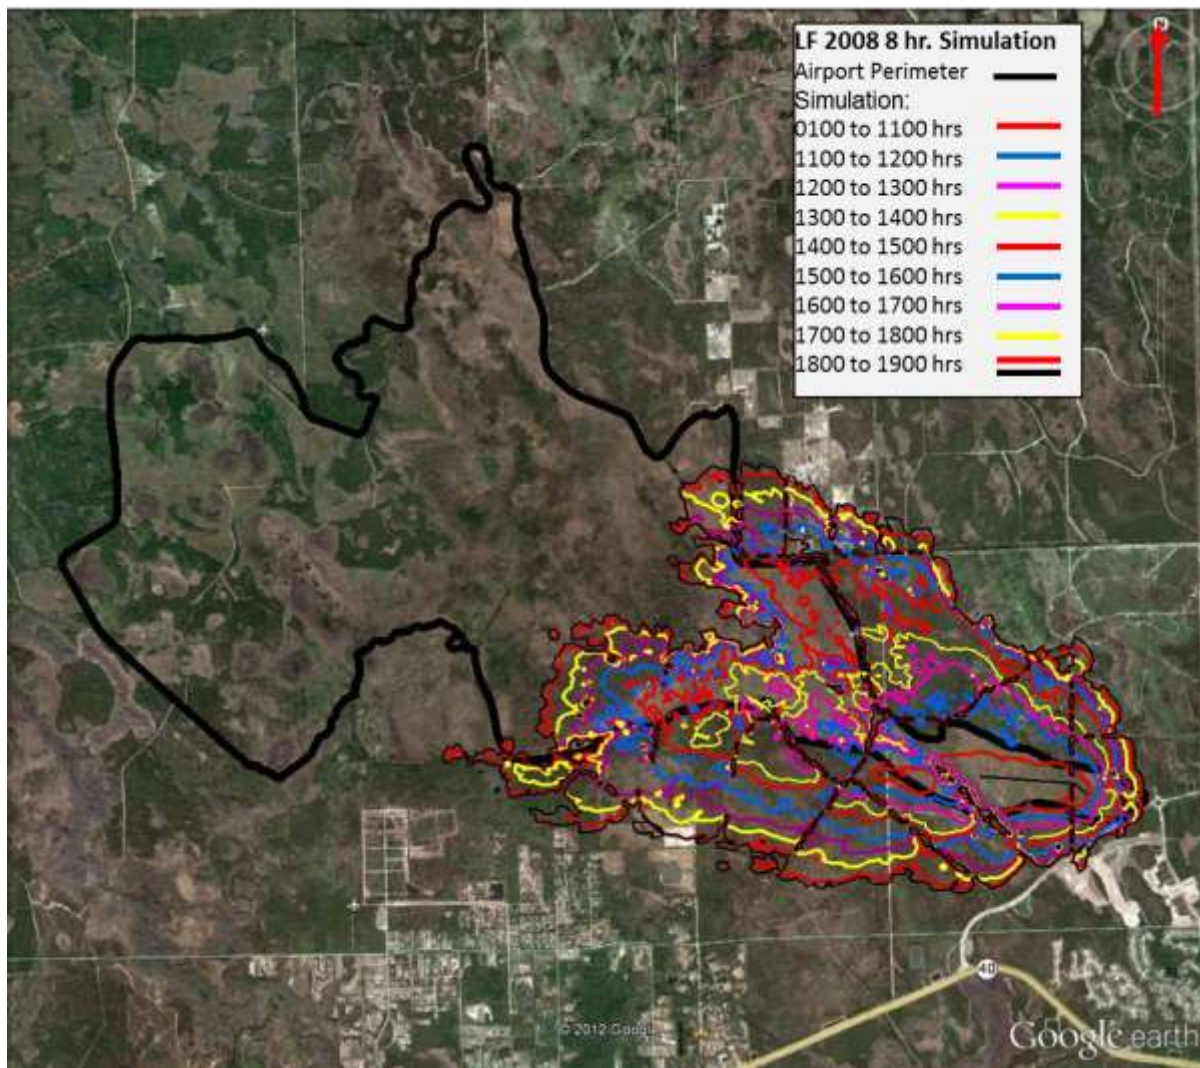

Figure 23 – LF 2008 Simulation of Post Airport Road Fire Landscape. The main burn area of the fire extended nearly 10 kilometers from northwest to southeast.

The following projection in Figure 24 was completed using two burn periods of 8 hours each. This analysis was done because it was not clear what time period the actual perimeters represented. The 2-day projection was completed on the LF 2001 landscape representing pre-fire conditions and was done for May 7th and May 8th with a maximum burn period from 1100 to 1900 hours on each day. The wind and weather conditions from the Lake George RAWS were used for those dates and included the 10-minute average wind speeds. The simulation results are depicted in Figure 24, but fall short of the final fire perimeter. The fire progression expansion rings are wider in the middle of the fire area, but fall short of the actual perimeter due to the slower modeled spread in the timber models of TU3, TL6, and TL2. A fire barrier file was constructed and used for the origin area of the fire to limit the fire spread and mimic the final fire perimeter.

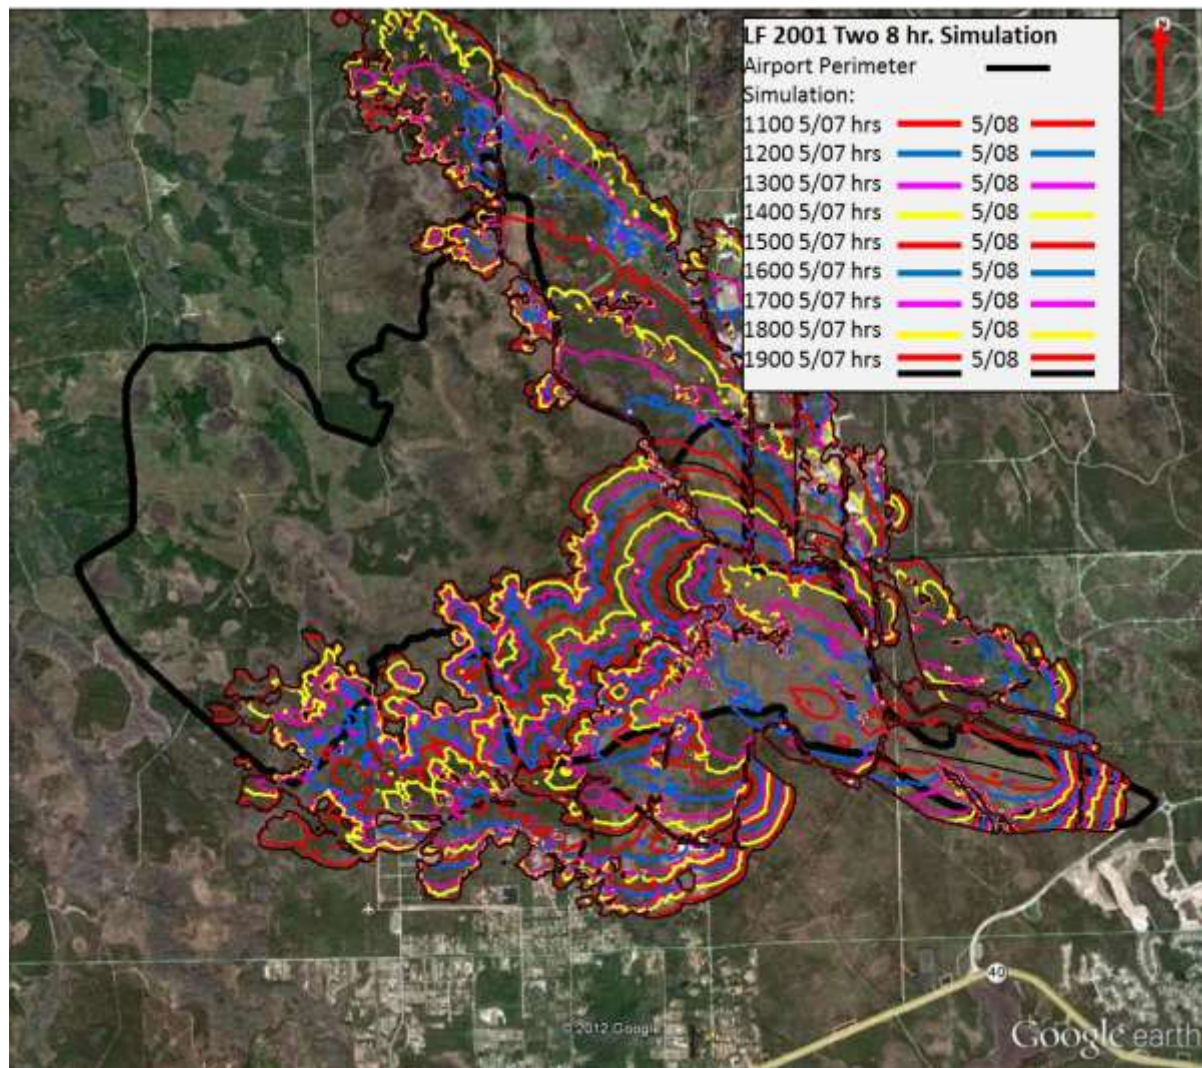

Figure 24 – Two day projection of Airport Road Fire on LF 2001 Landscape. The main burn area of the fire extended nearly 10 kilometers from northwest to southeast.

Because the timber models (TU3, TL6, and TL2 as described above) in the interior of the fire were not displaying the type of torching and crowning activity needed for the fire to mimic the final fire perimeter, an additional simulation was performed with lower canopy base heights. The CBH was lowered in the LF 2001 landscape and the simulation was set for one burn period at 8 hours. The same fuel moistures, lower wind speeds, and fire origin barrier file that were used in the previous projections were used for this simulation. The results in Figure 25 depict hourly expansion rings that were considerably larger in the timber fuel models in the center of the fire area with considerable spotting (from torching) and some crowning. This simulation more closely represented the actual fire extent as reported on May 8th. LANDFIRE data were developed for the average fire conditions to enable fire planners and managers to adjust the data up to reflect more extreme conditions if warranted. These results (Figures 21-24) are representative of what may happen when simulations are conducted for locations that have higher National Fire Danger Rating indices (above the 97th percentile as reported above). As such, analysts and managers need to similarly evaluate conditions and results when doing simulations.

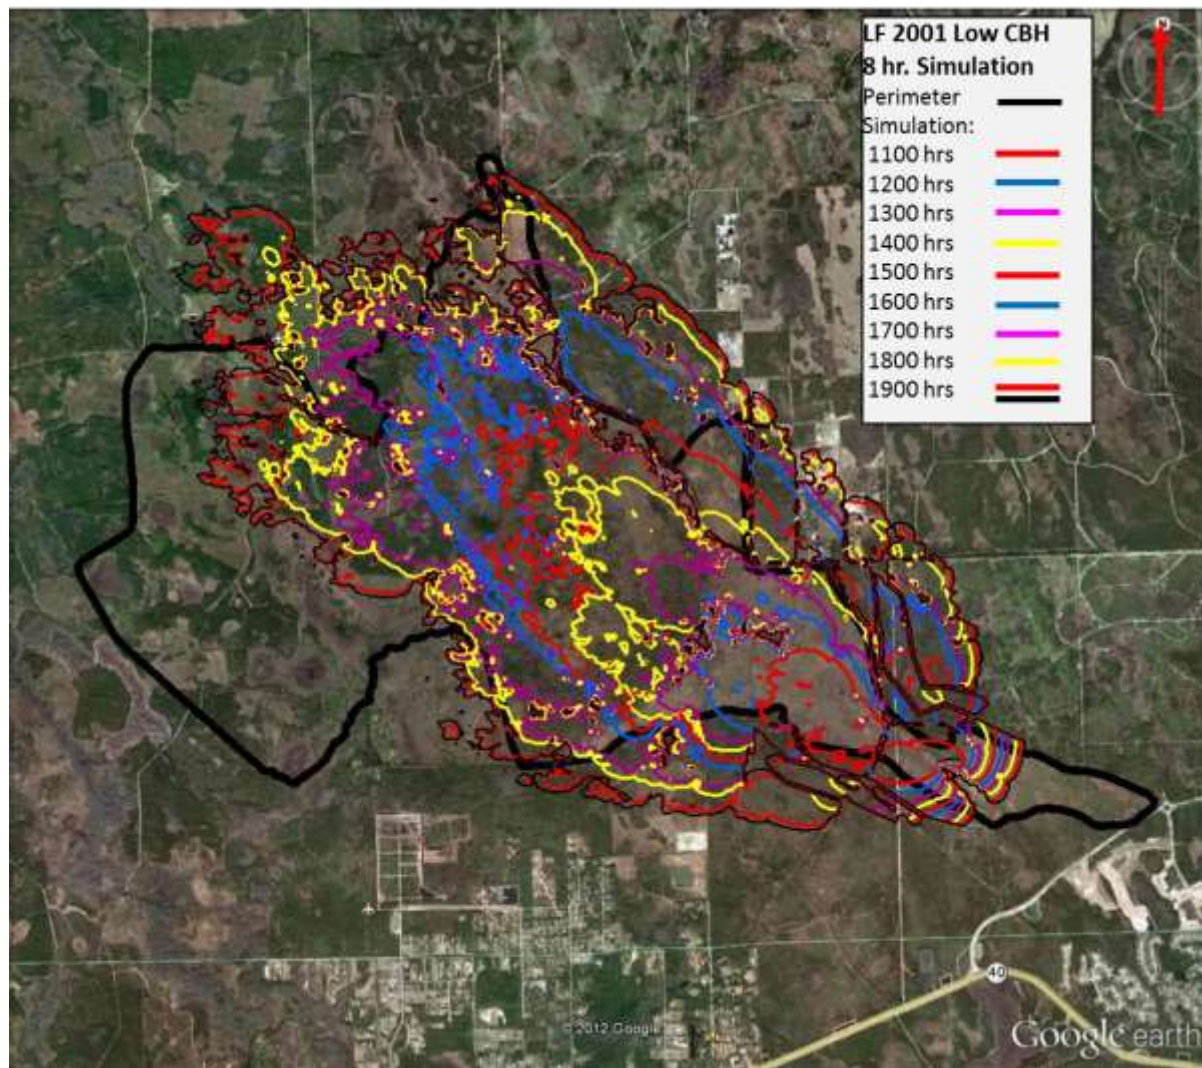

Figure 25– Airport Road Fire on LF 2001 landscape with CBH x .2 and 8 Hour Burn Period. The main burn area of the fire extended nearly 10 kilometers from northwest to southeast.

3.2 Unnamed Fire, MS, 2008

An Unnamed Fire occurred in south-central Mississippi (LF map zone 99) 23 miles southeast of Hattiesburg in the middle of March 2008 on private lands. There was not much information available about the fire in terms of suppression actions, origin, or progression and the only known fire perimeter was from March 16th. The final fire size was slightly greater than 4,280 acres. The ERC-G was well above average for this date over a 10-year period and the area indices were trending toward the 90th percentile. Most of the fire perimeter was along main roadways, so it was assumed that most of the suppression activities, including burning out or use of fuel breaks, may have occurred in this area.

The vegetation for approximately 70% of the fire area was described in the LF data as being composed of East Gulf Coastal Plain Interior Upland Longleaf Pine woodland (EVT 2349). Approximately 20% of the vegetation was composed of Gulf and Atlantic Coastal Plain Small Stream Riparian Systems (EVT 2474). The remaining 10% of vegetation was fairly equally divided between, Managed Tree Plantation-Southeast Conifer and Hardwood Group (EVT 2535), Gulf and Southern Coastal Plain Seepage Swamp and Baygall (EVT 2461), and a variety of Introduced Upland Vegetation.

3.2.1 Inputs

The weather, wind, and fuel moisture data used in the fire simulations were from the Black Creek (near Wiggins, MS) and Greene (near Leakesville, MS) RAWSs, which were located in close proximity to the fire site. The wind speeds at the 20-ft (6 meter) level ranged from 8 to 12 mph and wind gusts were recorded into the upper 20 mph range with directions from the east and northeast. The hourly mid-point value between 10-minute average and maximum gust wind speed and wind direction values were used in the simulation. The Black Creek RAWS was used to obtain beginning dead fuel moisture but live herbaceous fuel moisture was adjusted to emulate pre to early green up conditions.

LF National and LF 2001Refresh differ in surface fuel models (FBFM40) within EVT 2349 - East Gulf Coastal Plain Interior Upland Longleaf Pine woodland, where the change in height causes the model to change from a Shrub (SH) 4 (144) to TU3 (163) in the respective versions. LF 2008 fuel models depicted the site after the fire event, most of the landscape within the fire area transitioned from SH4 and TU3 to TL8 (188). In all versions of the LANDFIRE data, the riparian and lower areas of the site were represented by TL6 (186) and TL2 (182). Some of the more open and grassy areas were represented by GR3 (103) and GR5 (105).

The CBH in LF National is generally 6 m and greater, whereas, in LF 2001 the CBH generally is less than 5 m, with some pixels being in the 2 m range. After the disturbance (which was captured in LF 2008), the CBH is generally the same as LF 2001.

The final extent of the fire was brought to the roads in the area that served as the control lines on March 16th, except for a portion of the northern boundary of the fire. Prior to that time, no readily available information existed for how long the fire burned. Several simulations were produced to represent both single burn periods and multiple burn periods. The following results provide simulation examples for each version of the LF Fuel data as an attempt to replicate a 2-day spread in two 8-hour maximum burn periods. The burn period length was derived from the hours of low fuel moistures and high wind speeds in the RAWS data. The ignition point was set to the northeast corner of the fire in all three versions of the LF data landscape files. Wind direction on the first day of the simulated fire spread (March 15th) suggested likely fire spread from northeast to southwest. In the model simulation, crown fire activity was set to the Scott and Reinhardt method (Scott and Reinhardt, 2001) and spotting was enabled at 1.0%. A fuel moisture and environmental conditioning period was used from March 11th through March 14th and the fire was simulated to occur on March 15th and 16th.

3.2.2 Results

The overview map for the unnamed fire (Figure 26) displays the general vegetation of the area, the managed portions, and the area of the fire's assumed origin.

Figure 26– Overview of Unnamed MS Fire Area. The main burn area of the fire extended nearly 6.5 kilometers from north to south.

The LF National FBFM40 layer had enough slow burning timber models (TL6, TL2) to keep the simulated fire from carrying the fire across the expanse of the final perimeter in two burn periods. There was little in the way of torching, spotting, or crowning occurring in the simulation due to the CBH values and low intensity from the surface fuel models (Figure 27).

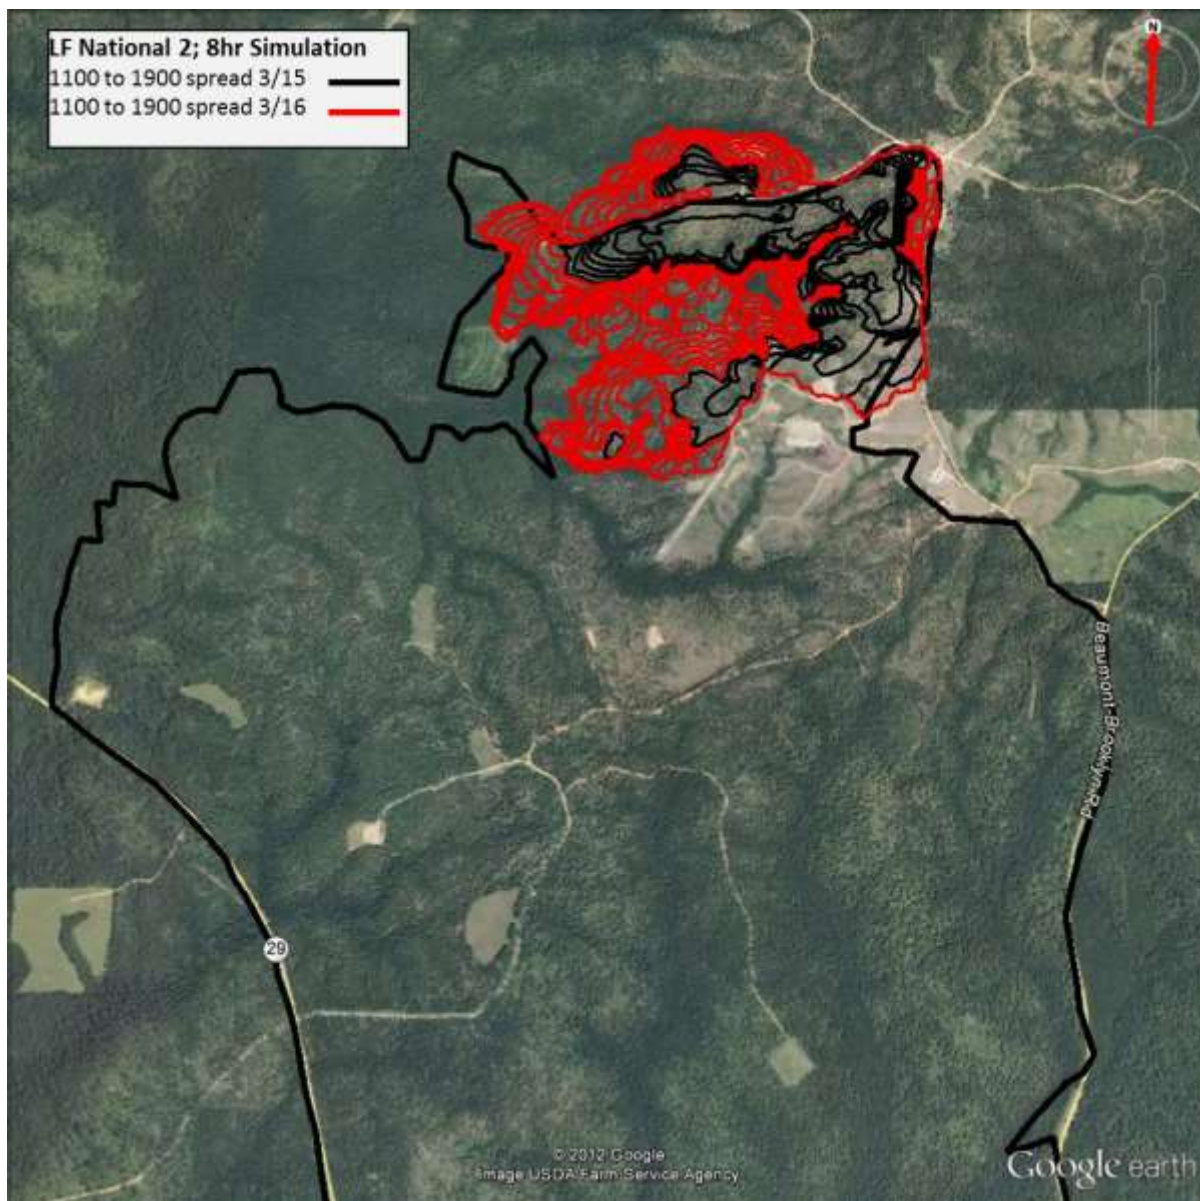

Figure 27– LF National Two Burn Period Simulated Spread. The main burn area of the fire extended nearly 6.5 kilometers from north to south.

Several simulations were completed on the LF 2001 landscape. The first (Figure 28) was with the unaltered landscape file that contained many areas of TU3 and SH4 around the fire origin area with somewhat lower CBHs (2 m to 5 m). The simulation did produce fire spotting, which was enough to cross the road into the developed area close by the fire origin, whereas LF National did not. This area was characterized in the fuel data as mainly heavy grass (GR) 5 and contributed substantially to the additional fire spread in the simulation. The two burn period simulation in the unaltered LF 2001 landscape (Figure 28) was similar to the Airport Road fire where the simulation fell short of the actual fire spread. There was no barrier file used in this simulation, so some fire spread outside the burn area was evident.

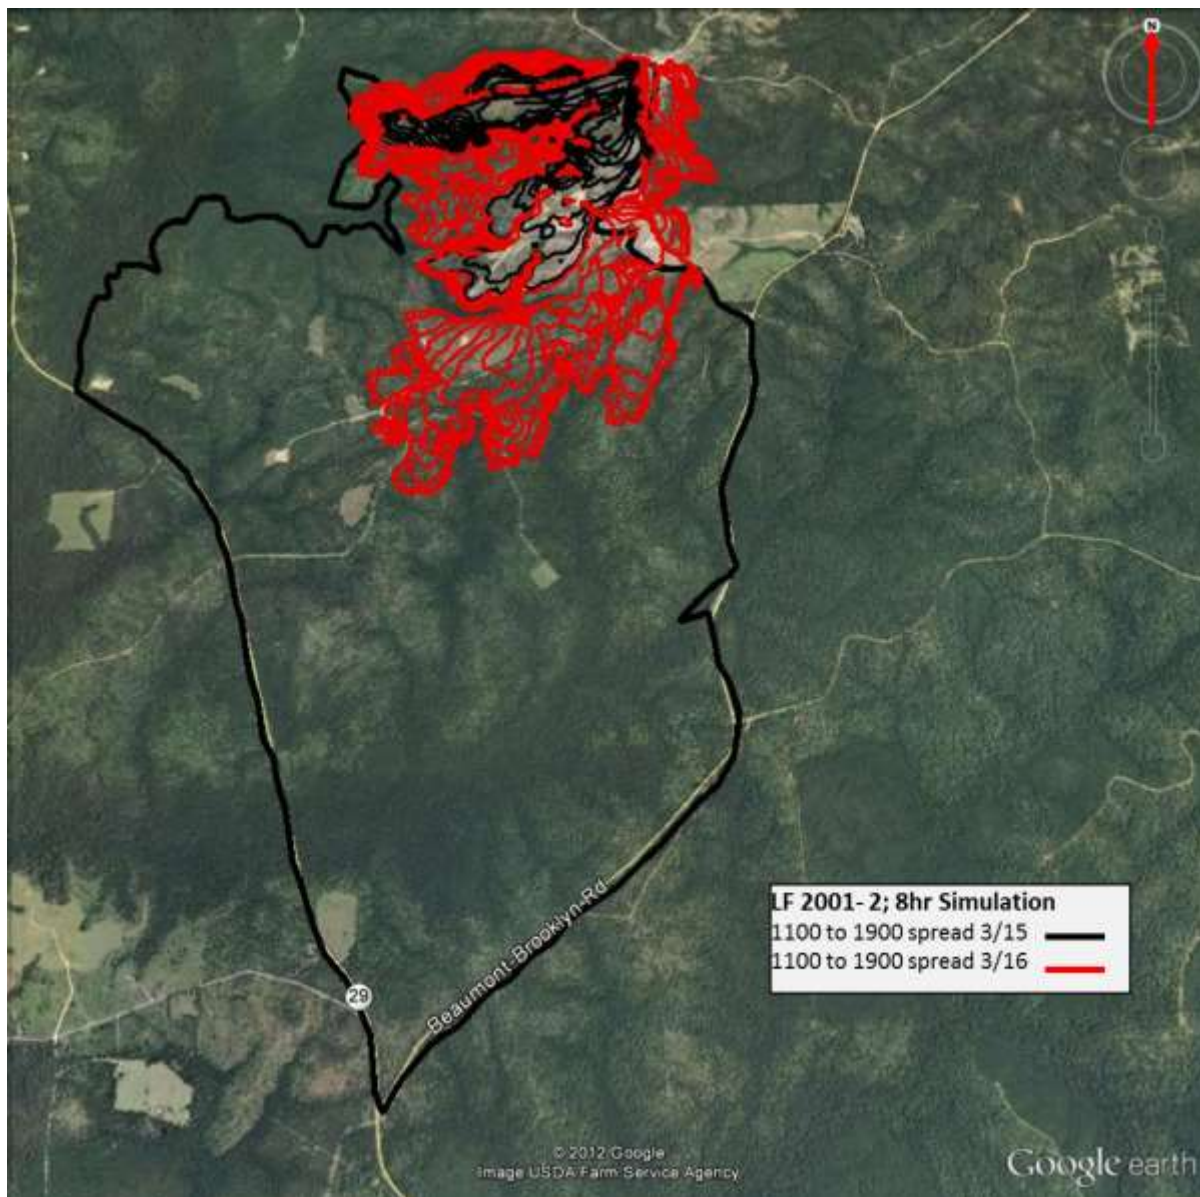

Figure 28– LF 2001 Landscape Two Burn Period Spread, No Barrier, and Moderate to High CBH. The main burn area of the fire extended nearly 6.5 kilometers from north to south.

Subsequent simulations on the LF 2001 landscape were accomplished with an altered CBH to increase crown fire activity within the model. While some of the CBH observed in the LF 2001 landscape were <3 m by the origin, most were above 3 m in the interior of the fire perimeter, which precluded crown fire activity. For a subsequent simulation, the CBH values were lowered to 20% of their original value to increase crowning fire within the interior of the fire perimeter. A 2-day simulation with the same environmental parameters was completed with this altered landscape and the results are displayed in Figure 29. Similar to the Airport Road Fire simulation, these model adjustments provided for a more representative fire extent, and analysts and managers need to similarly evaluate conditions and results when doing simulations.

Figure 29- Unnamed Fire LF 2001 Landscape Two Burn Period Simulation with Reduced CBH. The main burn area of the fire extended nearly 6.5 kilometers from north to south.

LF 2008 simulation (Figure 30) displays the expected fire activity within the site for the first 5 years after this event. The simulated fire was able to cross the road into the managed area and the fire spreads through the grass models quite readily. The timbered area, particularly in the riparian areas near the origin, tended to restrict fire spread. This restriction was a result of the LANDFIRE vegetation and fuel characteristics being updated to reflect disturbance conditions, e.g. Unnamed Fire that occurred in 2008. These updates provide managers and analysts with data sets that encompass these changes for disturbances across the landscape.

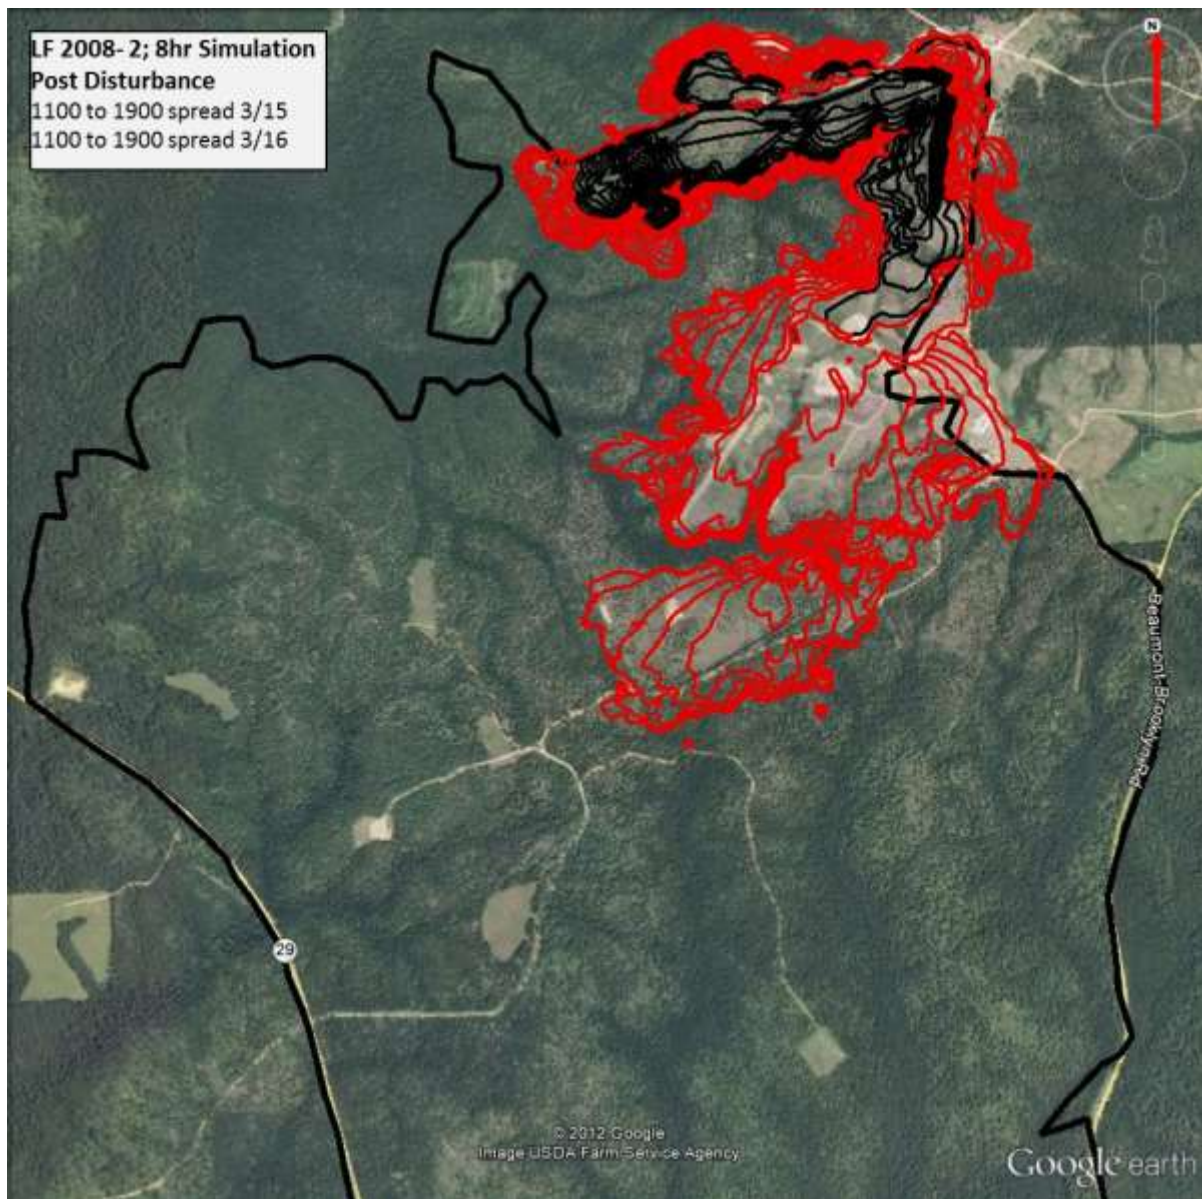

Figure 30- LF2008 Unnamed Fire Two Burn Period Simulated Spread- Post Disturbance. The main burn area of the fire extended nearly 6.5 kilometers from north to south.

5.0 Disclaimers

This report and associated LF data are provided "as-is" and without express or implied warranties as to their completeness, accuracy, suitability, or current state thereof for any specific purpose. The LF Program is in no way condoning or endorsing the application of these data for any given purpose. The DOI and USFS manage multiple sets of information and derived data as a service to users of digital geographic data and various databases. No agent of LF shall have liability or responsibility to data users or any other person or entity with respect to any loss or damage caused or alleged to be caused directly or indirectly by the data set. Any use of trade, firm, or product names is for descriptive purposes only and does not imply endorsement by the U.S. Government.

These data and related graphics (such as ".gif" or ".jpg" file formats) are not legal documents and are not intended to be used as such. Users take full responsibility for their applications of these data. It is the sole responsibility and obligation of the user to determine whether the data are suitable for the intended purpose and apply those data in an appropriate and conscientious manner.

LF is not obligated to provide updates to the data herein, as they are and shall remain consistent with those used to develop the LF Program products. However, the LF Program will, at its discretion, continue using these and previously supplied and sampled data to update and improve future versions of LF products. Users of these data are requested to inform the LF Program of significant errors to assist with product maintenance activities. Please send your feedback to helpdesk@landfire.gov.

6.0 Additional Information

This section lists some, but of course not all, partners that the LF Program works with and relies on for information and data.

6.1 Landsat

The Landsat program within USGS is a critical partner in the development of LF data products. The 30-meter Landsat imagery constitutes the foundation upon which all data layers were mapped as well as updated. When LF began in 2004, the cost of Landsat data greatly increased costs associated with the development of LF data products. Now that these data are free, costs have decreased and data improvement opportunities similar to the LF 2008 update process are expanding.

6.2 Forest Inventory Analysis

The FIA Program of the USFS provides key information to LF about America's forests. FIA provides a continuous forest census and reports on status and trends in forest area and location; in the species, size, and health of trees; in total tree growth, mortality, and removals by harvest; in wood production and utilization rates by various products; and in forest land ownership. Given the confidentiality of the FIA data, LF has a memorandum of understanding and supports an FIA employee who works with the FIA data, enabling LF to use this key resource. FIA has changed processes and procedures from a periodic survey to an annual survey and by expanding the scope of data collection to include soil, under story vegetation, tree crown conditions, CWD, and lichen community composition on a subsample of plots. LF will evaluate these data sets in the continual process to improve and update the LF data products.

6.3 National Agricultural Statistics Service

NASS provides valuable agriculture data for the entire United States. These data were extremely useful in assisting to delineate burnable and non-burnable agricultural lands. LF 2001/2008 used NASS CDL to refine the burnable/non-burnable lands data. LF and NASS will continue to work together in the future on additional LF data product improvements.

6.4 Multi-Resolution Land Characteristics Consortium National Land Cover Database

The Multi-Resolution Land Characteristics Consortium (MRLC) is a group of Federal agencies that coordinates and generates consistent and relevant land cover information at the national scale for a wide variety of environmental, land management, and modeling applications. The creation of this consortium (the LF Program is a member) has resulted in the mapping of a comprehensive land cover product, termed the NLCD, which is based upon a decadal composite of Landsat satellite imagery and other supplementary data sets.

LF has leveraged the MRLC NLCD2001 land cover product with the development of LF National (circa 2001) data and works to promote nationally complete, current, and consistent data across the Nation.

7.0 Glossary

FARSITE—Fire Area Simulator, a fire behavior and growth simulator

Fire Effects—The physical, biological, and ecological impacts of fire on the environment (NWCG 2005).

Fire Occurrence Database—A collection of information about fires including elements such as, date, location, acres, cause, etc.

Landsat Imagery—Thematic Mapper and Enhanced Thematic Mapper Plus image data from the Landsat 5 and Landsat 7 satellites, respectively. Image scenes have a footprint area of approximately 34,000 square kilometers and a pixel resolution of 30 meters.

Monitoring Trends in Burn Severity—Relevant spatial and non-spatial fire data are mapped by the MTBS project. Data elements include the latitude/longitude of the centroid of the MTBS burn scar perimeter.

Normalized Burn Ratio—an index similar to the Normalized Difference Vegetation Index. The primary difference is that NBR integrates the two Landsat bands that respond most, but in opposite ways to burning. The Landsat Thematic Mapper/Enhanced Thematic Mapper Plus bands used to calculate NBR are Band 4 and Band 7. The NBR is calculated as follows: $NBR = (4 - 7) / (4 + 7)$.

Prescribed Fire—Any fire ignited by management actions to meet specific objectives (NWCG 2005).

Remote Sensing Landscape Change— A process composed of four main elements. These are: 1) acquisition and compilation of field data; 2) wildfire burn mapping, as being conducted by the MTBS project; 3) updating and analysis using the VCT; and 4) mapping and incorporation of subtle intra-state changes, such as those related to insects and disease.

Spatial Resolution—The areal extent of the smallest unit, pixel, or feature that can be resolved on an image, map, or surface. Typically expressed as a measure of distance – for example, a 30-meter pixel – but can also be expressed as a unit of area.

Vegetation Change Tracker— The VCT is an automated and highly efficient algorithm for mapping changes in forest cover. The algorithm uses Landsat time series stacks, which are defined as sequences of Landsat images with a nominal temporal interval (for example, one image every year or every two years) for a particular location.

Wildfire—An unplanned, unwanted wildland fire, including unauthorized human-caused fires, escaped wildland fire use events, escaped prescribed fire projects, and all other wildland fires where the objective is to put the fire out (NWCG 2005).

Wildland Fire—Any non-structure fire that occurs in the wildland. Three distinct types of wildland fire have been defined and include wildfire, wildland fire use, and prescribed fire (NWCG 2005).

8.0 Acronyms

8.1 Acronyms for Agencies and Organizations

Agencies and Organizations	
BIA – Bureau of Indian Affairs	BLM – Bureau of Land Management
DOI – Department of the Interior	FWS – U. S. Fish and Wildlife Service

GAP – Gap Analysis Program – USGS	GLM – General Linear Model
GR – Grass	GS – Grass-shrub
HI – Hawaii	hrs. – hours
HUC – Hydrologic Unit Code	IR – Infrared
LCP – FARSITE landscape file	LF – LANDFIRE
LFRDB – LANDFIRE Reference Database	LTSS – Landsat Time Series Stacks
MFRI – Mean Fire Return Interval	MRLC – Multi-Resolution Land Characteristics Consortium
MTBS – Monitoring Trends in Burn Severity	MTBS – Monitoring Trends in Burn Severity
MTDB – Model Tracker Database	NBR – Normalized Burn Ratio
NC – North Central	NE – Northeast
NFDRS – National Fire Danger Rating System	NLCD – National Land Cover Database
PAD-US – Protected Area Database of the United States	PLS – Percent of Low-Severity fire

Acronyms

PM2.5 – total fine particulate matter emissions less than 2.5 micrometers in diameter	PMS – Percent of Mixed-Severity fire
PNW – Pacific Northwest	PRS – Percent Replacement-Severity fire
PSW – Pacific Southwest	QA/QC – Quality Assurance / Quality Control
RAVG – Rapid Assessment of Vegetation Condition after Wildfire	RAWS – Remote Automated Weather Station
RMT – Refresh Model Tracker (LF 2001/2008)	RSLC – Remote Sensing of Landscape Change
SC – South Central	SCLASS – Succession Class
SE – Southeast	SH – Shrub
SOW – Statement of Work	SSURGO – Soil Survey Geographic Database
SW – Southwest	TL – Timber litter
TU – Timber-understory	VCC – Vegetation Condition Class formerly known as LF FRCC
VCT – Vegetation Change Tracker	VDDT – Vegetation Dynamics Development Tool
VDEP – Vegetation Departure Index formerly known as LF FRCC Departure Index	VTDB – Vegetation Transition Data Base
WBS – Work Breakdown Structure	WFAT – Wildland Fire Assessment Tool
